(1) The little schalmey, he says, rarely employed: it measured about 17 inches in length, and had six lateral holes. Its deepest note was  (2) The discant schalmey (fig. 1), the primitive type of the modern oboe; its length was about 26 inches, and its deepest note  (3) The alto pommer (fig. 2), 30½ inches long, with its deepest note  (4) The tenor pommer (fig. 3), measuring about 4 feet 4 inches; besides the six lateral holes of the preceding numbers there were four keys which gave the grave notes  (5) The bass pommer, having a length of nearly 6 feet, and six lateral holes and four keys which gave  (6) The great double quint pommer, measuring about 9 feet 8 inches in length; the four keys permitted the production of the notes  These instruments, and especially numbers (2), (3), (4), and (5), occupied an important place on the Continent in the instrumental combinations of the last three centuries. The following illustration (fig. 4), borrowed from a picture,[1] painted in 1610 by Van Alsloot, represents six musicians playing the following instruments indicated in the order of their position in the picture: a bass oboe, bent over and become the bassoon, an alto pommer, a cornet (German "zinke"), a discant schalmey, a second alto pommer, and a trombone.[2]

  

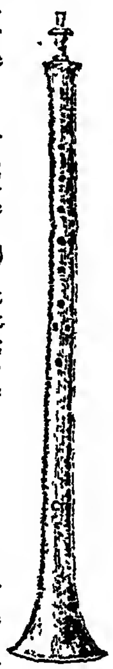

Fig. 1. The discant Schalmey. Fig. 2. The alto Pommer. Fig. 3. The tenor Pommer.

The 17th century brought no great changes in the construction of the four smaller instruments of the family.

[1] This picture, belonging to the National Museum of Madrid, represents a procession of all the religious orders in the city of Antwerp on the festival of the Virgin of the Rosary.

[2] For further details see Mahillon's catalogue of the *Musée du Conservatoire royal de musique de Bruxelles*.

Of much extended use in France, they were there called "haulx bois," or "haultbois," to distinguish them from the two larger instruments which were designated by the

Fig. 4.

words "gros bois." Haultbois became hautbois in French, and oboe in English, German, and Italian; and this word is now used to distinguish the present smaller instrument of the family.

The little schalmey and tenor pommer seem to have disappeared in the 17th century; it is the discant schalmey and the alto pommer which by improvement have become two important elements in modern instrumentation. The oboe, as such, was employed for the first time in 1671, in the orchestra of the Paris opera in *Pomone* by Cambert. The first two keys, , date from the end of the 17th century. In 1727 Gerhard Hoffmann of Rastenberg added the keys . A Parisian maker, Delusse, furnished, at the end of the 18th century, much appreciated improvements in the boring of the instrument. The *Méthode* of Sellner, published at Vienna in 1825, allows nine keys, , and one which, when opened, established a loop or ventral segment of vibration in the column of air, facilitating the production of sounds in the octave higher. Triebert of Paris owes his great reputation to the numerous improvements he introduced in the construction of the oboe.

The alto pommer became but slowly transformed: it was Oboe di called in French "hautbois de chasse," in Italian "oboe caccia. di caccia." In the 18th century we find it more elegant in form, but with all the defects of the primitive instrument. The idea of bending the instrument into a half circular form to facilitate the handling is attributed to an oboist of Bergamo, one Jean Perlendis, who was established at Strasburg about 1760. The fact of the instrument's resembling a kind of hunting-horn used at that time in England probably gained for it the name of "corno inglese," which it still retains ("cor anglais" in French). Cor The first employment of it in the orchestra is referred to anglais. Gluck, who had two "cors anglais" in his *Alceste*, as played at Vienna in 1767. But it was not until 1808 that the cor anglais was first heard in the Paris opera; it was played by the oboist Vogt in *Alexandre chez Apelle* by Catel. The improvements in manufacture of this instrument closely followed those introduced in the oboe. The 18th century produced an intermediate oboe between (2) and (3), which was called "hautbois d'amour," and was frequently employed by J. S. Bach. It was a third lower than the ordinary oboe, and fell into disuse after the death of the great German composer. It has been resuscitated by the firm of C.

Mahillon of Brussels, and reconstructed with the improvements of modern manufacture.

After the 16th century we find the instruments which were designated by the name of "gros bois," the (5) and (6) of Prætorius, transformed into shorter instruments, the fagott and contrafagott; so called because the column of air, the same as in the pommer, was formed of two conical tubes which communicated with the lower part of the instrument, and were pierced in a single piece of wood. It is probably owing to the aspect of this double pipe that the satirical name of fagot was given, preserved in Italian as fagotto, and in German as fagott. A canon of Ferrara named Afranio has been cited as the author of the transformation, about 1539, of the bass pommer, but Count Valdrighi, the curator of the Estense library,[1] and Wasielewski,[2] who has reproduced the drawing of Afranio's invention, deprive him of the merit of the innovation. The fagottino is transformed in the same fashion.

Fagott.

Bassoon.

Sigismund Scheitzer of Nuremberg acquired a great reputation in the 16th century for making the "basson," a French word substituted for the old fagot, and adopted in England as bassoon. His instrument had only two keys, . We cannot tell when the bassoon gained its present form, but it was probably at the end of the 17th century. It was made in exactly the same style as the fagottino represented in fig. 5. It appeared for the first time

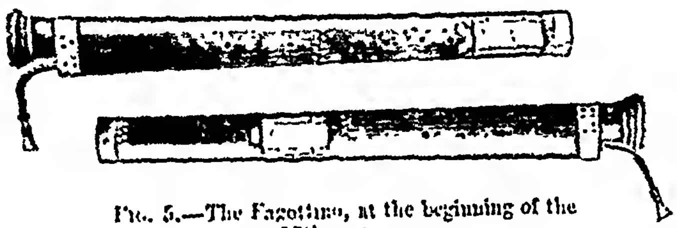

FIG. 5.—The Fagottino, at the beginning of the 17th century.

in the orchestra with the oboe in *Pomone* (1671). It had three keys then, . The B♭ key rendering a lengthening of the instrument necessary, we may suppose it took its modern form at that epoch. The fourth key, , dates from 1751. The bassoon appears with four keys in the *Encyclopédie* of Diderot and D'Alembert (Paris, 1751-65). The number of keys increased by the beginning of the present century to eight, viz., , and two keys to facilitate the production of acute harmonics. It has since been improved by Almenrader in Germany, Savari, and more recently Triebert and Goumas, Paris, and C. Mahillon, Brussels.

The reform in the construction of the flute due to Theobald Boehm of Munich about 1840, a reform which principally consisted in the rational division of the tube by the position of the lateral holes, prompted Triebert to try to adapt the innovation to the oboes and bassoons; but he failed, because the application of it denaturalized the timbre of the instruments, which it was necessary, before all things, to preserve. But his efforts did not remain sterile. In 1856 a French bandmaster, M. Sarrus, thought out the construction of a family of brass instruments with conical tubes pierced at regular distances, which, diminishing the length of the air column, has rendered a series of fundamental sounds easy,—more equal and free in timbre than that of the oboe family. Gautrot of Paris realized the inventor's idea, and, under the name of "sarrusophones," has created a complete family, from the sopranino in E♭ to the contrabass in B♭, of which his firm preserves the monopoly.

In 1868 the firm of C. Mahillon, Brussels, produced a reed contrabass of metal, destined to replace the old contrabassoon of wood, since much used in orchestras and military bands. The first idea of this instrument goes back to 1839, and is attributed to Schollnast and Son of Pressburg. It is a conical brass tube of very large proportions, with lateral holes placed as theory demands, in geometrical relation, with a diameter almost equal to the section of the tube at the point where the hole is cut. From this it results that for each sound one key only is required, and the seventeen keys give the player almost the facility of a keyboard. The compass written for this contrabass is comprised between  and , but sounds an octave lower.

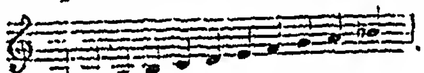
Cla

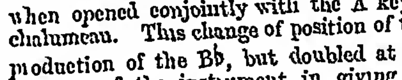
We now turn to another kind of reed and its association with two kinds of cylindrical and conical pipes,—the beating reed, which is formed of a single tongue, and engenders vibrations in the column of air to which it is applied by the contact of the tongue with the frame of a groove to which it is adapted. The beating reed, though not having the extreme antiquity of the *double reed*, was used at a very early period, for we find it applied to the chalumeaus of ancient Egypt, still in use under the name of *arghoul*, to the Greek *auloi*, and the Roman *tibiæ*.[3] The beating reed is a piece of reed growth, closed at the upper end by the natural knot, beneath which a tongue is partly detached by a longitudinal slit. We do not see the probable operation of chance so clearly here as in the double reed. It may have been the inconvenience resulting from the employment of double-tongued reeds of large dimensions to make cylindrical pipes of a certain diameter speak that urged the invention of a more commodious substitute. With double *auloi* it would have been almost impossible to blow two double reeds at one time, while, on the contrary, it is easy to sound two pipes furnished with beating reeds introduced simultaneously into the player's mouth. Such as these are the actual Egyptian *arghoul* and *zummârah*. It is in the beating reed and cylindrical tube, a combination bequeathed to us by remote antiquity, that we find the principle of one of the leading instruments of the modern orchestra, the clarinet or clarionet.

The European chalumeau of the Middle Ages, in English "shawm," differed but little from the ancient Egyptian chalumeau: its tube was of wood, and the upper part of the tube communicated with the bore by an opening made laterally and longitudinally, on the edges of which the reed-tongue was bound by repeated turns of string. Neither in the Middle Ages nor in the 16th century do we find the chalumeau much employed. Prætorius, who in his *Theatrum instrumentorum* has given exact drawings of the instruments he knew, does not cite the chalumeau. But there exists in the fine collection of the Liceo Musicale at Bologna a double chalumeau of wood covered with leather, the make of which takes it back to the 16th century. Drawings of this instrument occur in the *Encyclopédie* of Diderot and D'Alembert, and in the *Muzykaal Kunstwoordenbock* of J. Verschuere-Reynvaan (Amsterdam, 1795). The chalumeau was pierced with eight holes and with two keys, and produced the following series of fundamental sounds—



The present writer has had the good fortune to find quite recently two examples in the National Museum at Munich, and has been kindly authorized by Herr von Hefner-Alteneck, director of the museum, to reproduce them for the museum of the conservatoire at Brussels. For one of these see fig. 6. It is from this reproduction that he has been enabled to determine the exact nature of the improvement of the chalumeau, about 1690, by Christopher Denner of Nuremberg, an improvement which has gained for him the reputation of having invented the clarinet. Every clarinet player knows that it is sufficient for one of the upper keys not to quite close the hole for it to produce, instead of the fundamental sound, the interval of the twelfth above it,—in other words, the second partial. This phenomenon is easily explained: the communication between the external air and the upper part of the air-column in the instrument forms a ventral segment or loop of vibration and forces the column to divide, and, as a cylindrical pipe affected by a reed sounds harmonically after the manner of stopped pipes, the possible partial after the fundamental is naturally the second. This phenomenon must have struck Denner, and have suggested to him the idea of obtaining the same result according to a regular manner and at the will of the executant. He arrived at it by raising a little the key governed by the thumb of the left hand, which when opened conjointly with the A key produced the B♭ of the chalumeau. This change of position of the key did not hinder the production of the B♭, but doubled at one stroke the extent of compass of the instrument in giving it the following notes—

FIG. 6.—The Chalumeau.



This was Denner's invention; he did not invent the clarinet, but he was the first to make use of the artifice already referred to which permits instruments of cylindrical bore to produce fundamental sounds and their twelfths.

[3] F. A. Gevaert, *Histoire de la musique dans l'antiquité.*

About the middle of last century the clarinet was lengthened and a key was added, , which filled the vacant space between the two registers. Two new keys were also added, , it is said, by Barthold Fritz of Brunswick (*ob.*

FIG. 7.—The Clarinet.

1766). The sixth key, , is attributed to the clarinetist Lefebvre. Paris, about 1791. In 1810 Ivan Muller carried the number of keys up to thirteen, in which state the instrument has come to us, and is the system most employed. It has been improved by the Belgian makers, Bachmann, the elder Sax, C. Mahillon, and Albert, who have collectively established the reputation of Belgian clarinets. In Paris, Lefebvre, Buffet-Crampon, and his successor Goumas—in London, Rudall, Rose, and Carte, justly own a high position among famous clarinet-makers. The firm of C. Mahillon, Brussels, have invented the mechanism with double effect known by the name of C♯ key. Invented in 1862, it is now universally adopted. In 1842 the Parisian maker Buffet, advised by a professor named Klosé, adopted from Boehm's flute the invention of movable rings. His clarinet has consequently been ranked as of Boehm's system, although the lateral division of the tube does not follow that which that clever maker applied to his flute. The clarinet was first employed in a theatre in 1751. in the pastoral by Rameau entitled *Acante et Cephise*. The imperfections of the instrument at that time obliged them to be made in nearly every key. To avoid the burden of this the 18th-century players varied the key of their instruments by added joints. About the middle of the 18th century the clarinet was introduced in military music and by degrees supplanted the oboe. The instruments used at first were in C and F. About 1815 they were replaced by the B♭ and E♭ clarinets.

Basset horn. Besides the high clarinets, the basset horn (Italian, corno di bassetto) was soon known in Germany; a clarinet in F with the grave fifth of the one in C, it was made to descend easily to  with the help of supplementary keys, and to diminish the length of the tube it was bent back upon itself in the part nearest to the bell,—the curve being enclosed in a kind of box which concealed the artifice. The invention of the basset horn is attributed to a Bavarian maker at Passau, who was living about 1770, but whose name is now unknown. Obtaining the improvements given to it by Theodore Lotz of Pressburg in 1782, and Ivan Muller in 1812, and those of contemporary makers, the basset horn has become the beautiful alto clarinet which is generally used in the key of E♭.

It would appear that the first idea of the bass clarinet emanated from Henri Greuser of Dresden, who made the first one in 1793 It was not used in the orchestra until 1836, when Meyerbeer made magnificent employment of it in the *Huguenots*.

Clarinet d'amour. The almost forgotten clarinet d'amour was made in G and F, the fourth and fifth below the clarinet in C. It differed from other clarinets in the bell, which, retracted in the lower part, affected the pear-shaped contour that distinguishes the modern cor anglais.

Saxophone. A few words remain to be said about the combination of the beating reed with a conical tube, which goes no farther back than the beginning of this century. A fagottino in F, called "dolcino," was at that time used, the air-column of which was more decidedly conical than that of the fagottino properly so called. The double reed was replaced in it by a beating reed attached to a mouthpiece like that of the clarinet but smaller. This instrument seems not to have had success. But the most important combination of beating reed and conical tube was accomplished in 1846 by Adolphe Sax, a Belgian established in Paris, who invented the family of saxophones. This instrument is a brass tube pierced to produce the following

scale—
In virtue of the principle previously explained, the saxophone "octaves," and, setting out from the fourth fundamental, each note can be reproduced in the next upper octave by the help of two keys successively employed, which, by opening, form a loop. Four more keys disposed at the upper end permit the production of , which completes the compass of the saxophone. Four instruments of the saxophone family are now used, viz., the soprano in B♭, a major second below the note written; the alto in E♭, a fifth below the soprano; the tenor in B♭, an octave below the soprano: and the baritone in E♭, an octave below the alto. These instruments fill an important place in the military music of France and Belgium. The brilliant success which Ambroise Thomas has achieved by using the beautiful tone of the alto saxophone in the ghost scene in *Hamlet* is well known. (V. M.)

O'BRIEN, WILLIAM SMITH (1803-1864), the head of the "Young Ireland" party. was born on 17th October 1803, and received his education at Harrow and at Cambridge. He entered parliament in 1826 as member for Ennis, and from 1835 to 1848 represented the county of Limerick. Although he spoke in 1828 in favour of Catholic emancipation, he for many years continued to differ on other points from the general policy of O'Connell. He, however, opposed the Irish Arms Act of 1843, and in January 1844 became an active member of the Repeal Association. Though he was destitute of oratorical gifts, his chivalrous devotion to the welfare of his country secured him enthusiastic attachment as a popular leader. In July 1846 he with the "Young Ireland" party left the Repeal Association, and in the beginning of 1847 he established the Irish Confederation. The French Revolution of 1848 stimulated his hopes of success, and incited him to more extreme efforts against the English rule. In May 1848 he was tried at Dublin for sedition, but the jury disagreed. In the following July he established a war directory, and attempted to make a rising among the peasantry of Ballingarry, but although he was at first joined by a large following the movement wanted cohesion, and the vacillating crowd dispersed as soon as news reached them of the approach of the dragoons. O'Brien was arrested at Thurles, tried, and sentenced to death. The sentence was commuted to transportation for life. In July 1854 he received his liberty on condition of never revisiting the United Kingdom; and in May 1856 he obtained a full pardon. Henceforth he kept aloof from all political movements. In 1856 he published *Principles of Government, or Meditations in Exile*. He died at Bangor, North Wales, 18th June 1864.

OBSERVATORY

Up to a comparatively recent date an "observatory" was a place exclusively devoted to the taking of astronomical observations, although frequently a rough account of the weather was kept. When the progress of terrestrial magnetism and meteorology began to make regular observations necessary, the duty of taking these was often thrown on astronomical observatories, although in some cases separate institutions were created for the purpose. Of late years, as the work to be done in astronomical observatories is increasing, there seems to be a general tendency to have the magnetical and meteorological observations taken in separate establishments; but, as the exclusively magnetical or meteorological observatories now existing are generally very small institutions and of recent creation, the astronomical observatories will be chiefly considered in this article.

Up to about 300 B.C. it can scarcely be said that an observatory existed anywhere, as the crude observations

of the heavens then taken were only made by individuals and at intervals, employing the simplest possible apparatuses. But, when philosophical speculation had exhausted its resources, and an accumulation of facts was found to be necessary before the knowledge of the construction of the universe could advance farther, the first observatory was founded at Alexandria, and continued in activity for about four hundred years, or until the middle or end of the 2d century of the Christian era. It was here that Hipparchus, the founder of modern astronomy, by repeating observations made by his predecessors, discovered the precession of the equinoxes, and investigated with considerable success the motions of the sun, moon, and planets. His work was continued by more or less distinguished astronomers, until Ptolemy (in the 2d century A.D.) gave the astronomy of Alexandria its final development. When science again began to be cultivated after the dark ages which followed, we find several observatories founded by Arabian princes: first one at Baghdad (and possibly one at Damascus), built by the caliph Al-Mamún early in the 9th century, then one on the Mokattam near Cairo, built for Ion Yúnis by the caliph Ḥákim (about 1000 A.D.), where the Ḥákimite tables of the sun, moon, and planets were constructed. The Mongol khans followed the example; thus arose the splendid observatory at Merágha in the north-west of Persia, founded about 1260 A.D. by Hulagu Khan, where Násir al-dín Ṭúsi constructed the Ilohkhanic tables; and in the 15th century the observatory at Samarkand was founded by Ulug Begh, and served not only in the construction of new planetary tables but also in the formation of a new catalogue of stars.

With the commencement of scientific studies in Europe in the 15th century the necessity of astronomical observations became at once felt, as they afforded the only hope of improving the theory of the motions of the celestial bodies. Although astronomy was taught in all universities, the taking of observations was for two hundred years left to private individuals. The first observatory in Europe was erected at Nuremberg in 1472 by a wealthy citizen, Bernhard Walther, who for some years enjoyed the co-operation of the celebrated astronomer Regiomontanus. At this observatory, where the work was continued till the founder's death in 1504, many new methods of observing were invented, so that the revival of practical astronomy may be dated from its foundation. The two celebrated observatories of the 16th century, Tycho Brahe's on the Danish island of Huen (in activity from 1576 to 1597) and that of Landgrave William IV. at Cassel (1561-97), made a complete revolution in the art of observing. While the credit of having vastly improved the astronomical instruments perhaps should be divided equally between Tycho Brahe and the landgrave's astronomer Bürgi, the former may claim the honour of having been the first to see the necessity of carrying on for a number of years an extensive and carefully-planned series of observations with various instruments, worked by himself and a staff of assistants. In this respect his observatory (Uraniburgum) resembles our modern larger institutions more closely than do many observatories of much more recent date. The mighty impulse which Tycho Brahe gave to practical astronomy at last installed this science at the universities, among which those of Leyden and Copenhagen were the first to found observatories. We still find a large private observatory in the middle of the 17th century, that of Johannes Hevelius at Dantzic, but the foundation of the royal observatories at Paris and Greenwich and of numerous university observatories shows how rapidly the importance of observations had become recognized by governments and public bodies, and it is not until within the last hundred years that the development of various new branches of astronomy has enabled private observers to compete with public institutions.

The instruments employed in observatories have of course changed considerably during the last two hundred years. When the first royal observatories were founded, the principal instruments were the mural quadrant for measuring meridian zenith distances of stars, and the sextant for measuring distances of stars *inter se*, with a view of determining their difference of right ascension by a simple calculation. These instruments were introduced by Tycho Brahe, but were subsequently much improved by the addition of telescopes and micrometers. When the law of gravitation was discovered it became necessary to test the correctness of the theoretical conclusions drawn from it as to the motions within the solar system, and this necessarily added to the importance of observations. By degrees, as theory progressed, it made greater demands for the accuracy of observations, and accordingly the instruments had to be improved. The transit instrument superseded the sextant and offered the advantage of furnishing the difference of right ascension directly; the clocks and chronometers were greatly improved; and lastly astronomers began early in the 19th century to treat their instruments, not as faultless apparatuses but as imperfect ones, whose errors of construction had to be detected, studied, and taken into account before the results of observations could be used to test the theory. This century has also witnessed the combination of the transit instrument and the mural quadrant or circle in one instrument,—the transit or meridian circle.

While the necessity of following the sun, moon, and planets as regularly as possible increased the daily work of observatories, other branches of astronomy were opened and demanded other observations. Hitherto observations of the "fixed stars" had been supposed to be of little importance beyond fixing points of comparison for observations of the movable bodies. But when many of the fixed stars were found to be endowed with "proper motion," it became necessary to include them among the objects of constant attention, and in their turn the hitherto totally neglected telescopic stars had to be observed with precision, when they were required as comparison stars for comets or minor planets. Thus the field of work for meridian instruments became very considerably enlarged.

In addition to this, the increase of optical power of telescopes revealed hitherto unknown objects—double stars and nebulæ—and brought the study of the physical constitution of the heavenly bodies within the range of observatory work. Researches connected with these matters were, however, for a number of years chiefly left to amateur observers, and it is only within the last fifty years that many public observatories have taken up this kind of work. The application of spectrum analysis, photography, photometry, &c., in astronomy has still more increased the number and variety of observations to be made, so that it has now become necessary for most observatories to devote themselves to one or two special fields of work.

It would be difficult to arrange the existing observatories into classes either according to the work pursued in them or their organization, as the work in many cases at different times has been directed to different objects, while the organization depends mostly on national and local circumstances. As already alluded to above, one of the principal characteristics of the larger observatories of the present day is the distribution of the work among a number of assistants under the general superintendence of a director. This applies principally to the great observatories, where the sun, moon, planets, and a limited number of fixed stars are without interruption being observed, but even among

these institutions hardly two are conducted on the same principles. Thus in Greenwich the instruments and observations are all treated according to strict rules laid down by the astronomer-royal, while in Washington or Pulkowa each astronomer has to a certain extent his choice as to the treatment of the instrument and arrangement of the observations. The same is the case with the smaller institutions, in most of which these arrangements vary very much with change of personnel.

The way in which the results of observations are published depends principally on the size of the institutions. The larger observatories issue their "Annals" or "Observations" as separate periodically-published volumes, while the smaller ones chiefly depend on scientific journals to lay their results before the public, naturally less fully as to details. Among these journals the principal are:—*Berliner Astronomisches Jahrbuch* (for the years 1776 to 1829), *Monatliche Correspondenz* (edited by Von Zach, 28 vols., 1800-13), *Astronomische Nachrichten* (founded 1821; 107 vols. in 4to, still appearing with two vols. per annum), *Memoirs of the Royal Astronomical Society* (47 vols. 4to, from 1822), and *Monthly Notices of the Royal Astronomical Society* (44 vols. 8vo, from 1827).

Subjoined is a catalogue of public and private observatories now in activity or which have existed within the last hundred years. ($4^m = 1°$ long.)

Great Britain and Ireland.

A. Public Observatories.

Greenwich, royal observatory, lat + 51° 28′ 38″·4. Founded in 1675 for the promotion of astronomy and navigation. The observations have therefore from the first been principally intended to determine the positions of standard stars, the sun and planets, and above all to follow the motion of the moon with as little interruption as possible, both on and outside the meridian. Since 1873 spectroscopic observations and a daily photographic record of sun-spots have been taken. The observatory is under the direction of the astronomer-royal; and from the time of its first astronomer, Flamsteed, the institution has always maintained its place in the foremost rank of observatories. Thus the observations of Bradley (*ob.* 1762) form the foundation of modern stellar astronomy; but it was especially during the directorship of Airy (1835-81) that the observatory rose to its present high state of efficiency. There are now a chief assistant, eight assistants, and a staff of computers employed. The principal instruments now in use are:—a meridian circle by Simms (and Ransomes and May as engineers), erected in 1850, having a circle of 6-feet diameter and a telescope of 8-inches aperture; a large chronograph (1854); an altazimuth by Simms and Ransomes and May, for observations of the moon, erected in 1847, with 3-feet circles and 4-inch telescope; an equatorial refractor by the same makers (O.G. 12·8 inches, by Merz), mounted in the "English" manner with long polar axis, chiefly used for spectroscopic work; photoheliograph by Dallmeyer of 4-inches aperture, smaller equatorials, clocks, &c. The standard "motor clock" is the centre of a system of electrically-controlled clocks scattered over many provincial towns in the three kingdoms. The magnetical and meteorological department was founded in 1838; it contains a complete set of instruments giving continuous photographic records of magnetic declination, horizontal and vertical force, barometric pressure, dry and wet bulb thermometers, &c. The *Observations* are published with all details from 1750, beginning with 1836 in annual bulky 4to volumes; special results—*e.g.*, five *Star Catalogues*, *Reductions of Lunar and Planetary Observations*—are published in separate volumes.

Oxford, Radcliffe Observatory, lat + 51° 45′ 36″·0, long. $0^h 5^m 2^s·6$ W. Founded in 1771 by the Radcliffe trustees at the instance of Professor Hornsby. Observations were regularly made, but none were published until Manuel J. Johnson was appointed Radcliffe observer in 1839, when systematic observations were commenced with an 8-feet transit instrument by Bird (1773) and a 6-feet mural circle by Jones (1836). Johnson was succeeded in 1860 by Rev. R. Main, who died in 1878, and was followed in 1879 by E. J. Stone. Heliometer (7½ inch) by Repsold (1849); meridian circle by Troughton and Simms, mounted in 1861, formerly belonging to Mr Carrington; self-recording meteorological instruments. The staff now consists of three assistants. Besides the annual 8vo volumes of *Observations* (from 1840), two catalogues of respectively 6317 and 2386 stars, chiefly circumpolar (1860 and 1870) have been published.

Oxford, university observatory, lat. + 51° 45′ 34″·2, long. $0^h 5^m 0^s·4$ W. Finished in 1875; is under the Savilian professor of astronomy; there are two assistants. 12¼-inch equatorial refractor by Grubb, and a 13-inch reflector made and presented by Mr De La Rue. The former is used for micrometer work (chiefly on clusters of stars) and photometric observations; the latter for taking lunar photographs, by means of which the director, Professor Pritchard, has investigated the libration of the moon. No. 1 of *Astronomical Observations* (8vo) was published in 1878.

Cambridge, lat. + 52° 12′ 51″·6, long. $0^h 0^m 22^s·8$ E. Founded by the university senate in 1820. Directors: G. B. Airy, 1828 to 1835; J. Challis, to 1861; J. C. Adams. Chiefly devoted to meridian work,—up to 1870 with a 5-inch transit by Dollond and a mural circle by Jones; a new meridian circle by Simms, of 8-inches aperture and 3-feet circles, was then erected, and is being used for determining the places of all the stars down to 9·0 mag. between + 25° and + 30° decl. The "Northumberland equatorial" was mounted in the "English" fashion in 1838; the object-glass by Cauchoix is of 11½-inches aperture and 19-feet focal length. The *Observations* from 1828 to 1865 are published in 21 4to volumes.

Durham, lat. + 54° 46′ 6″·2, long. $0^h 6^m 19^s·8$ W. Founded in 1841, principally by private subscription; is under the direction of the professor of mathematics and astronomy in the university. There is a small meridian circle by Simms, and an equatorial refractor by Fraunhofer of 6½-inches aperture, with which minor planets, comets, and double stars have been observed. The results from the years 1846-52 have been published in 2 8vo volumes.

Liverpool (Bidston near Birkenhead), lat. + 53° 24′ 4″, long. $0^h 12^m 17^s·2$ W. Founded in 1838 by the municipal council; transferred in 1856 to the Docks and Harbour Board; moved to Birkenhead in 1867. Specially intended for testing the rates of chronometers under different temperatures. Transit instrument by Troughton and Simms, and an 8-inch equatorial by Merz.

Kew (Richmond), lat. + 51° 28′ 6″, long. $0^h 1^m 15^s·1$ W. The central meteorological observatory of the United Kingdom, with self-registering meteorological and magnetical instruments. Established in 1842 under the auspices of the British Association, afterwards transferred to the Royal Society. A photoheliograph was employed at Mr De La Rue's expense to take daily sun-pictures from 1863 to 1872.

Edinburgh, royal observatory, lat. + 55° 57′ 23″·2, long. $0^h 12^m 43^s·0$ W. Founded in 1811 by subscription; the building on the Calton Hill erected in 1818. In 1834 the founders handed over the administration to the Government, and in 1846 the ownership was similarly transferred. Since 1834 the observatory has been under the direction of the astronomer-royal for Scotland, who is also professor of practical astronomy in the university; there are two assistants. Professor T. Henderson (1833 to 1845) commenced extensive meridian observations of fixed stars, since continued by his successor, C. Piazzi Smyth. The mural circle of 6-feet diameter and 8-feet transit are now out of date. A reflector of 2-feet aperture by Grubb (silver on glass) was erected in 1872, but has never been quite finished nor come into use. Observations with deep-soil thermometers have been carried on since 1837, and delicate spectroscopic investigations made by the present astronomer, partly abroad. Observations and results have been published in 14 4to volumes.

Glasgow, lat. + 55° 52′ 42″·8, long. $0^h 17^m 10^s·6$ W. Organized in 1840 by subscription, aided by subsidies from the university and the state; is under the professor of astronomy. Meridian circle by Ertel with 42-inch circles, and telescope of 6-inches aperture; equatorial of 9-inches aperture. A catalogue of 6415 stars from meridian observations made since 1860 was published in 1883 by the present director, R. Grant. The observatory was (1868-83) one of the seven first-class meteorological stations.

Dublin, situated about 4 miles north-west of Dublin at Dunsink, lat. + 53° 23′ 13″·0, long. $0^h 25^m 21^s$ W. Belongs to the university; erected in 1785; is under the direction of the "Andrews professor of astronomy and royal astronomer of Ireland." There is one assistant. In 1808 a reversible meridian circle by Ramsden and Berge of 8-feet diameter was put up, with which Brinkley observed assiduously till 1827, though of his results those relating to stellar parallax were affected by certain instrumental errors which rendered them of no value. Sir W. R. Hamilton (1827-65) devoted himself exclusively to mathematics. In 1868 was erected an equatorial refractor, object-glass of 11¾-inches aperture by Cauchoix (formerly belonging to and given by Sir J. South), which has been used by Brunnow and his successor R. S. Ball (since 1874) for researches on stellar parallax. A meridian circle by Pistor and Martins of 6·4-inches aperture was mounted in 1873 and a large chronograph in 1882; they are used for observing stars possessing special interest (red stars, stars with proper motion, &c.). *Astronomical Observations and Researches made at Dunsink*, parts 1-5, 4to, 1870-84.

Armagh, lat. + 54° 21′ 12″·7, long. $0^h 26^m 35^s·5$ W. Founded and endowed by Archbishop Robinson in 1791. Possessed very few instruments until the observatory was enlarged by Archbishop Lord John Beresford in 1827, when a mural circle and a transit by Jones were provided, with which T. R. Robinson (director from 1823 to 1882) observed the stars contained in the catalogue of 5345

stars published in 1859. With the mural circle, to which had been added a 7-inch telescope by T. Grubb (in 1862), about 3000 stars have been observed since 1864, and these are now (1884) ready for press. There is also a 15-inch reflector. Armagh was (1868-83) one of the seven first-class meteorological observatories.

Cork, observatory of Queen's College, lat. + 51° 53′ 30″, long. 0h 33m 58s W. Erected in 1878 at the expense of Mr Crawford of Cork; 8-inch refractor, 4-inch siderostat and transit circle, by Grubb. Managed by the professor of natural philosophy.

B. Private Observatories now existing.

Mr J. G. Barclay's observatory, Leyton, Essex, lat. + 51° 34′ 34″, long. 0h 0m 0s·9 W. In activity since 1862; 10-inch refractor by Cooke; chiefly devoted to double stars; small transit circle. Four parts of *Observations* have been published (4to, 1863-77).

Mr A. A. Common's observatory, Ealing, London, W. Silvered-glass reflector of 36-inches aperture (mirror by Calver, mounting by the owner), erected in 1879; chiefly used for celestial photography. Also 18-inch silvered-glass reflector erected in 1876.

Colonel Cooper's observatory, Markree Castle, Sligo, Ireland, lat. 54° 10′ 31″·8, long. 0h 33m 48s·4 W. Founded by the late E. J. Cooper, who in 1834 erected an equatorial refractor of 13·3-inches aperture (glass by Cauchoix). In addition to numerous other observations this instrument was from 1848 to 1856 used for determining the approximate places of 60,000 stars near the ecliptic (*Markree Catalogue*, 4 vols. 8vo, 1852-56). The observatory was restored in 1874, and the refractor has since been used for double-star observations. There is also a transit circle by Ertel.

Earl of Crawford's observatory, Dun Echt, Aberdeenshire, lat. + 57° 9′ 36″, long. 0h 9m 40s W. Founded in 1872; is one of the best-equipped observatories existing; has 15-inch equatorial refractor by Grubb, large chronograph (driven by same clock as the refractor), 12-inch silvered reflector by Browning, two 6-inch and several smaller refractors, meridian circle by Simms similar to the one at Cambridge, numerous spectroscopes and minor instruments, also a large library, and a collection of physical instruments. Cometary and spectroscopic observations and reduction of the observations made by the Venus expedition to Mauritius in 1874 have hitherto principally occupied the staff. Three 4to volumes of *Publications* and very frequent *Dun Echt Circulars*, distributing news of discoveries (chiefly relating to comets), have been issued.

Mr E. Crossley's observatory, Bermerside, Halifax, Yorkshire. Equatorial refractor by Cooke of 9·3-inches aperture, erected in 1871, chiefly used for observations of double stars.

Dr W. Huggins's observatory, Upper Tulse Hill, London, lat. + 51° 26′ 47″, long. 0h 0m 27s·7 W. Founded in 1856; furnished with an 8-inch refractor (glass by Clark, mounting by Cooke). In 1870 was erected an equatorial mounting which could carry either a 15-inch refractor or a Cassegrain reflector of 18-inches aperture, both made by Grubb for the Royal Society; mounting improved in 1882 to carry both instruments simultaneously. With these Dr Huggins has made his well-known spectroscopic observations and photographs of stellar spectra, the solar corona, &c., the results being published from time to time in the *Philosophical Transactions*.

Mr G. Knott's observatory, Cuckfield, Sussex (from 1860 to 1873 at Woodcroft, lat. + 51° 0′ 41″, long. 0h 0m 34s W., since then at Knowles Lodge, Cuckfield). 7·3-inch refractor by Clark, used for observing double stars and variable stars.

Mr R. S. Newall's observatory, Gateshead, Newcastle-on-Tyne. A refractor of 25-inches aperture by Cooke was mounted in 1870, but appears to have been little used.

Earl of Rosse's observatory, Birr Castle, King's county, Ireland, lat. + 53° 5′ 47″, long. 0h 31m 40s·9 W. In 1839 the late earl made and mounted a reflector of 3-feet aperture (remounted as equatorial in 1876), and in 1845 he completed the celebrated reflector of 6-feet aperture and 54-feet focal length. These instruments, particularly the latter, were used from 1848 to 1878 for observations of nebulæ, and revealed many new features in these bodies; results published in the *Phil. Trans.* for 1844, 1850, 1861, 1868, and collected systematically in the *Trans. Roy. Dubl. Soc.*, 1879-80. Experiments were made by the present earl to determine the amount of heat radiated from the moon (*Phil. Trans.*, 1873).

Rugby School (Temple Observatory). Founded in 1872 in memory of the bishop of Exeter; with 8¼-inch equatorial refractor by Clark, used for observations of double stars and of stellar spectra.

Stonyhurst College observatory, Lancashire, lat. + 53° 50′ 40″, long. 0h 9m 52s·7 W. An 8-inch equatorial refractor by Troughton and Simms, mounted in 1867, used for spectroscopic and micrometric observations; a complete set of self-recording magnetic instruments. From 1868 to 1883 the observatory was one of the seven first-class meteorological stations.

Colonel Tomline's observatory, at Orwell Park, Ipswich, lat. + 52° 0′ 33″, long. 0h 4m 55s·8 E. Founded in 1874; has a 10-inch refractor by Merz, used for observations of comets.

Owing to the limited space at our disposal we are obliged to pass over several smaller private observatories.

C. Private Observatories now discontinued.

Mr Bishop's observatory, South Villa, Regent's Park, London, lat. + 51° 31′ 29″·9, long. 0h 0m 37s·1 W. In activity from 1836 to 1861, then removed to Twickenham, and discontinued in 1874; has a 7-inch refractor by Dollond, with which Mr Hind discovered ten minor planets and several comets, and constructed maps of stars near the ecliptic.

Mr R. C. Carrington's observatory, Redhill, lat. + 51° 14′ 25″·3, long. 0h 0m 41s·3 W. Established in 1854; has a 4½-inch refractor, and transit circle of 5-inch aperture (now at Radcliffe Observatory). With the latter a catalogue of the positions of 3735 stars within 9° of the pole, with the former regular observations of sun-spots, were made from 1853 to 1861.

Rev. W. R. Dawes's observatory, first at Ormskirk (1830-39), lat. + 53° 34′ 18″, long. 0h 11m 36s W.; afterwards at Cranbrook, Kent (1844-50), lat. + 51° 6′ 31″, long. 0h 2m 10s·8 E.; then at Wateringbury, near Maidstone, lat. + 51° 15′ 12″, long. 0h 1m 39s·8 E., till 1857; and finally at Hopefield, Haddenham, lat. + 51° 45′ 54″, long. 0h 3m 43s·4 W., till Mr Dawes's death in 1868. Possessed at first only small instruments, then successively a 6-inch refractor by Merz, a 7¼-inch and an 8¼-inch refractor by Clark, and an 8-inch refractor by Cooke, with all of which a great many measures of double stars were made, which were published in the *Memoirs* of the Royal Astronomical Society.

Mr De La Rue's observatory, Cranford, Middlesex, lat. + 51° 28′ 57″ 8, long. 0h 1m 37s·5 W. Established in 1857; with 13-inch reflector, devoted to solar and lunar photography. The Kew photoheliograph was employed here from 1858 to 1863 to take daily photographs of the sun. The reflector was presented to the Oxford observatory in 1874.

Mr Isaac Fletcher's observatory, Tarnbank, Cumberland, lat. + 54° 39′ 13″·7, long. 0h 13m 44s·5 W. Established in 1847; in 1859 a 9½-inch refractor by Cooke was mounted and used for observing double stars.

Mr Groombridge's observatory, Blackheath, lat. + 51° 28′ 2″·7, long. 0h 0m 0s·6 E. In 1806 Mr Groombridge obtained a new transit circle of 4-feet diameter by Troughton, with which he up to 1816 observed stars within 50° of the pole. The resulting catalogue of 4243 stars was published in 1838.

Sir William and Sir John Herschel's observatory at Slough near Windsor, lat. + 51° 30′ 20″, long. 0h 2m 24s W. William Herschel settled at Datchet in 1782, and at Slough in 1786, and erected several 20-feet reflectors (of 18-inches aperture), and in 1789 his 40-feet reflector of 4-feet aperture. The latter was comparatively little used (two satellites of Saturn were discovered with it), while the former served to discover about 2500 nebulæ and clusters, 800 double stars, and two satellites of Uranus, as also to make the innumerable other observations which have made the name of Herschel so celebrated. Sir J. Herschel used a 20-feet reflector at Slough from 1825 to 1833, and from 1834 to 1838 at the Cape of Good Hope, to examine the nebulæ and double stars of the whole of the visible heavens, discovering 2100 new nebulæ and 5500 new double stars.

Rev. T. J. Hussey's observatory, Hayes, Kent, lat. + 51° 22′ 38″, long. 0h 0m 3s 6 E. In activity from about 1825 for about twelve years: 6½-inch refractor by Fraunhofer, used for making one of the star maps published by the Berlin Academy, also small transit circle by Simms.

Mr Lassell's observatory, from about 1820 to 1861 at Starfield near Liverpool, lat. + 53° 25′ 28″, long. 0h 11m 38s·7 W.; contained reflectors of 9 and 24 inches aperture; employed for observations of the satellites of Saturn, Uranus, and Neptune, and of nebulæ. The 2-feet reflector was used at Malta in 1852-53, and a 4-feet reflector was mounted in 1861, also at Malta, and used till 1864 for observations of satellites and nebulæ. The eighth satellite of Saturn, the two *inner* satellites of Uranus, and the satellite of Neptune were discovered at Starfield by Mr Lassell.

Dr Lee's observatory, Hartwell, Bucks, lat. + 51° 48′ 36″, long. 0h 3m 24s·3 W. In 1836 Dr Lee came into possession of Captain Smyth's 6-inch refractor, and mounted it at Hartwell House, where it continued to be occasionally employed for double-star observations and other work up to about 1864.

Captain Smyth's observatory, Bedford, lat. + 52° 8′ 27″·6, long. 0h 1m 52s·0 W. In 1830 Captain (afterwards Admiral) Smyth erected a 6-inch refractor by Tulley, and observed the double stars and nebulæ contained in his "Bedford Catalogue" (1844), forming vol. ii. of his *Cycle of Celestial Objects*.

Sir James South's observatory, from 1816 to 1824 at Blackman Street, Southwark, long. 0h 0m 21s 8 W. Here South took transit observations of the sun, and he and J. Herschel measured double stars, in 1821-23. In 1826 South erected an observatory at Campden Hill, Kensington, lat. + 51° 30′ 12″, long. 0h 0m 46s 8 W., and procured a 12-inch object-glass from Cauchoix. As Troughton, however, failed to make a satisfactory mounting, the glass was

never used until after it had been presented to Dublin university in 1862.

Lord Wrottesley's observatory, from 1829 to 1841 at Blackheath, lat. + 51° 28′ 2″, long. 0h 0m 2s·7 E., where a catalogue of the right ascensions of 1318 stars was formed from observations with a transit instrument by Jones. In 1842 a new observatory was built at Wrottesley Hall, lat. + 52° 37′ 2″·3, long. 0h 8m 53s·6 W., where the transit and a 7¾-inch refractor by Dollond were mounted. Observations were here made of double stars, and for testing J. Herschel's method of finding the annual parallax of stars.

FRANCE.

Paris, national observatory, lat. + 48° 50′ 11″·8, long. 0h 9m 20s·9 E. Founded in 1667, when the construction of a large and monumental building was commenced by the architect Perrault. J. D. Cassini's observations made the institution for some time the most celebrated observatory existing, but later the activity declined, although several eminent men, as Bouvard and Arago, have held the post of director. Since 1854, when Leverrier assumed the directorship, the observations have been conducted with more regularity, and, together with a number of most important theoretical works, published in the *Annals* (35 volumes of *Observations*, 16 of *Memoirs*). The observations are now chiefly taken in order to redetermine the positions of Lalande's 50,000 stars. The principal instruments now in use are:—a meridian circle by Secretan and Eichens, with an object-glass of 9·5-inches aperture and 12-feet focal length, another by Eichens (given by M. Bischoffsheim) of 7·5-inches aperture and 7-feet focal length, a 15-inch equatorial refractor by Lerebours and Brünner, a 12-inch equatorial refractor by Secretan and Eichens, two refractors of 9·5-inches aperture, &c. A refractor of 29-inches aperture by Martin is being mounted. A silvered glass reflector of 4-feet aperture was mounted in 1875, but has never been used. The meteorological bureau was after Leverrier's death (1877) separated from the observatory.

In addition to this national observatory there were during the latter half of last century several minor observatories in Paris, which only lasted for some years. Among these were the observatory at *Collège Mazarin*, lat. + 48° 51′ 29″, where Lacaille observed from 1746 to 1750, and from 1754 to 1762, and the observatory at the *École Militaire*, lat. + 48° 51′ 5″, built in 1768 and furnished with an 8-feet mural quadrant by Bird, with which D'Agelet observed telescopic stars (1782-85), and which was afterwards (1789-1801), under Lalande's direction, employed for observing more than 50,000 stars, published in the *Histoire Céleste* (1801).

Meudon, close to Paris Founded in 1875; devoted to physical astronomy, and especially to celestial photography, under the direction of J. Janssen.

Montsouris, situated in the Montsouris Park, south of Paris, lat. + 48° 49′ 18″, long. 0h 9m 20s·7 E. Founded in 1875 for the training of naval officers.

Lyons, old observatory in lat. 45° 45′ 46″, long. 0h 19m 18s E., at the Jesuit college. A new observatory was erected in 1877 at St Génis-Laval, at some distance from the city. Transit circle by Eichens (2-feet circles, 6-inch O.G.), 6-inch refractor by Brunner.

Marseilles, lat. 43° 18′ 19″·1, long. 0h 21m 34s·8 E. Originally belonging to the Jesuits, taken over by the ministry of the navy in 1749. It was here that Pons made his numerous discoveries of comets. A new building was erected in 1869; 9½-inch equatorial refractor, reflector of 32-inches aperture and 16-feet focal length. The present director, Stephan, has discovered and micrometrically measured several hundred very faint nebulæ.

Toulouse, lat. 43° 36′ 47″·0, long. 0h 5m 51s·0 E. Erected in 1840 (Darquier had observed at the Lyceum towards the end of last century); restored a few years ago, when an equatorial refractor by Brünner was procured.

Nice, founded and endowed by M. Bischoffsheim for the Bureau de Longitude (1880), situated at Mont Gros, north-east of Nice. Is being furnished with first-class instruments, among which are a refractor of 30-inches aperture by Henry Brothers (mounting by Eichens), a meridian circle by Brunner of 8-inches aperture, and large spectroscopes, &c.

GERMANY.

Altona, lat. + 53° 32′ 45″·3, long. 0h 39m 46s·1 E. Founded in 1823 by the Danish Government to assist in the geodetic operations in Holstein. A meridian circle by Reichenbach (of 4-inches aperture and 3-feet circle) and several theodolites were procured, to which, in 1858, was added a 4½-inch equatorial by Repsold. The observatory is best known by the fact that the *Astronomische Nachrichten*, the principal astronomical journal, was published here from 1821 (by Schumacher up to 1850, by Peters from 1854). The observatory was moved to Kiel in 1872.

Berlin, royal observatory, lat. + 52° 30′ 16″·7, long. 0h 53m 34s·9 E. Was erected in 1705 as part of the building of the Academy of Sciences (lat. + 52° 31′ 12″·5, long. 0h 53m 35s E.), a very unsuitable locality. After the death of Bode in 1826, who had founded the *Astronomisches Jahrbuch* (from 1776), a new observatory was built in the southern part of the city under the direction of Encke, finished in 1835. With the observatory is now connected a computing office, where the *Jahrbuch* is edited. The instruments now in use are:—an equatorial refractor by Utzschneider and Fraunhofer, of 9-inches aperture and 14-feet focal length (with which Neptune was found in 1846 in the place indicated by Leverrier; used at present for observations of minor planets), a meridian circle by Pistor and Martins of 4-inches aperture (lately used by Auwers to observe stars between + 15° and + 25° decl.), another by the same makers of 7-inches aperture, now used to observe stars between + 25° and + 30° decl.

Bonn, university observatory, lat. + 50° 43′ 45″·0, long. 0h 28m 23s·3 E. Finished in 1845 (a temporary observatory had been used by Argelander from 1841 to observe stars from + 45° to + 80° decl.); meridian circle by Pistor of 4½-inches aperture, heliometer by Merz of 6-inches aperture. The former was used by Argelander for observing stars between − 15° and − 31° decl., and afterwards for determining 33,000 places of stars in the northern heavens. The observatory is chiefly known by the zone observations, made from 1852 to 1859 with a small comet-seeker, on which Argelander's great atlas of 324,198 stars between the North Pole and − 2° decl is founded; many other investigations on proper motions, variable stars, &c., were also made by Argelander. The zone work is now being continued with a 6-inch refractor from − 2° to − 31° decl. by the present director, Schonfeld, who had already, with Krüger, assisted Argelander in the northern zones. With the meridian circle stars between + 40° and + 50° decl. are now being observed. A new meridian circle of 6-inches aperture by Repsold has recently been mounted. Seven 4to volumes of *Observations* have been published.

Bothkamp, Herr von Bülow's observatory, lat. 54° 12′ 9″·6, long. 0h 40m 30s·8 E. Situated a few miles from Kiel, founded in 1870, the principal instrument being an equatorial refractor of 11-inches aperture by Schröder, with spectroscopic and photographic appliances, with which Dr Vogel obtained valuable results from 1871-74, published in three 4to parts of *Beobachtungen*. The observations have only quite recently been recommenced.

Bremen. In the third story of his house in Sandstrasse, Olbers (died 1840) had his observatory, lat. 53° 4′ 38″, long. 0h 35m 10s E.; though the principal instrument was only a 3¾-inch refractor by Dollond, many comets and the planets Pallas and Vesta were discovered and observed here.

Breslau, lat. + 51° 6′ 56″·1, long. 1h 8m 9s·1 E. In a small and unsuitable locality, where a few small instruments are placed.

Dresden, Baron von Engelhardt's observatory, lat. + 51° 2′ 16″·8, long. 0h 54m 54s·8 E. A 12-inch equatorial refractor by Grubb (mounted 1880), used for observations of comets and double stars.

Düsseldorf (Bilk, originally a suburb, now part of the city), lat. + 51° 12′ 25″, long. 0h 27m 5s·5 E. Founded and endowed by Professor Benzenberg (died 1846); best known by the discovery of twenty-one minor planets by R. Luther; the principal instrument is a 4½-inch refractor.

Gotha. In 1791 an observatory was founded by Duke Ernest II. at Seeberg, lat. + 50° 56′ 5″·2, long. 0h 42m 55s·8 E., on a hill a few miles from Gotha, the chief instrument being a large transit instrument by Ramsden. Though the labours, principally theoretical, of the successive directors, Zach, Lindenau, Encke, and Hansen, the institution ranked with the first observatories, but the distance from Gotha and the decay of the buildings made it necessary to build a new observatory at Gotha in 1857, lat. + 50° 56′ 37″·5, long. 0h 42m 50s·5 E. This observatory received the instruments from Seeberg, including a small transit circle by Ertel (made in 1824), also a new equatorial by Repsold of 4½-inches aperture.

Gottingen, university observatory, lat. + 51° 31′ 47″·9, long. 0h 39m 46s·5 E. An observatory had existed here during the 18th century, where Tobias Mayer worked. In 1811 a new building was constructed. Besides his mathematical works, Gauss found time to engage in important geodetic and magnetic observations. In 1867-69 a catalogue of stars between the equator and − 2° decl. was made by Copeland and Börgen. The principal instruments are a meridian circle by Repsold (4½-inches aperture), another by Reichenbach (4½-inches), several refractors from 3 to 5 inches aperture, &c.

Hamburg, lat. + 53° 33′ 7″·0, long. 0h 39m 53s·7 E. Built in the year 1825. With a meridian circle of 4-inches aperture by Repsold, C. Rumker observed the places of 12,000 stars. An equatorial refractor of 10-inches aperture was mounted in 1868, used for observations of star-clusters, comets, and minor planets.

Kiel, royal observatory, lat. + 54° 20′ 29″·7, long. 0h 40m 35s·8 E. Contains the instruments removed from Altona in 1872, also an 8-inch refractor by Steinheil. The office of the *Astronomische Nachrichten* has been here since 1872.

Konigsberg, university observatory, lat. + 54° 42′ 50″·6, long. 1h 21m 58s·9 E. Built 1813; Bessel was the director till his death in 1846, and nearly all his celebrated investigations were carried out here, *e.g.*, observations of fundamental stars, zone observations of stars from − 15° to + 45° decl., researches on refraction, heliometric observations, by which the annual parallax of the star 61

Cygni was first determined, &c., published in the first 21 volumes of the *Beobachtungen auf der k. Sternwarte zu Königsberg*. The instruments are a meridian circle by Reichenbach and Ertel of 4-inches aperture (mounted 1819), another of the same dimensions by Repsold (1841), a 6-inch heliometer by Utzschneider 1829, &c.

Leipsic, university observatory, lat. + 51° 20′ 20″·5, long. 0h 49m 33s·9 E. Erected 1787-90 on the "Pleissenburg"; possessed only small instruments, the largest being a 4½-inch refractor by Fraunhofer 1830, with which from 1848 d'Arrest observed minor planets, comets, and nebulæ. In 1861 a new observatory was erected under the direction of Bruhns, lat. + 51° 20′ 6″·3, long. 0h 49m 34s·1 E., with a refractor of 8½-inches aperture by Steinheil and a meridian circle by Pistor and Martins of 6½-inches aperture mounted. The former is used for observing double stars, nebulæ, and comets, the latter for observing stars between −5° and −15° decl. In 1881 Dr Engelmann mounted an 8-inch equatorial refractor by Clark and Repsold in a small private observatory close to the university observatory.

Lilienthal, near Bremen, lat. + 53° 8′ 25″, long. 0h 35m 32s E. J. H. Schröter's private observatory, from 1778 to 1813. Contained a number of reflectors by Herschel and Schrader, the largest being of 27-feet focal length and 20-inches aperture, movable round the eye-piece, used for physical observations, chiefly of planets. Destroyed during the war in 1813; the instruments, which had been bought by the Government in 1800, were, for the greater part, sent to the Göttingen observatory.

Mannheim, lat. + 49° 29′ 11″·2, long. 0h 33m 50s·5 E. Built in 1772; except C. Mayer's observations of distant companions to bright stars, very few observations were published until the observatory was restored in 1860, when a 6-inch refractor by Steinheil was procured, with which Schönfeld determined the positions of 500 nebulæ. In 1879 the observatory was moved to Karlsruhe.

Munich, at Bogenhausen, royal observatory, lat. + 48° 8′ 45″·5, long. 0h 46m 26s·1 E. Founded in 1809; a meridian circle by Reichenbach was mounted in 1824, an 11-inch equatorial refractor by Fraunhofer in 1835. The former was used from 1840 for zone observations, about 80,000 of telescopic stars, the resulting 34,000 places of which were published in six catalogues; the latter was for some years used by Lamont for observing satellites and nebulæ. Afterwards Lamont chiefly devoted his attention to terrestrial magnetism.

Potsdam, lat. + 52° 22′ 56″, long. 0h 52m 17s E. "Astrophysical observatory," founded in 1874, devoted to spectroscopic, photometric, and other physical observations. An equatorial refractor by Schröder of 11¾-inches aperture, another by Grubb of 8-inches aperture, spectroscopes, photometers, &c. Results are published in 4to volumes.

Speyer, observatory of the Lyceum, lat. + 49° 18′ 56″, long. 0h 33m 45s·3 E., established in 1827. With a meridian circle by Ertel, Schwerd observed in 1826-29 the positions of circumpolar stars. Discontinued many years ago.

Strasburg, university observatory, lat. + 48° 34′ 59″·7, long. 0h 31m 4s·7 E. Finished in 1881. Observations made in a temporary observatory from 1872; an 18-inch equatorial refractor by Merz; altazimuth of 5½-inches aperture, meridian circle of 6½-inches aperture, and a 6½-inch orbit sweeper, all by Repsold.

Wilhelmshaven, Prussia, naval observatory, lat. + 53° 31′ 52″·2, long. 0h 32m 35s·3 E., situated on the Jade to the north of Oldenburg. Founded in 1874; meridian circle by Repsold of 4½-inches aperture, and meteorological, magnetical, and tide-registering instruments.

Austria-Hungary.

Vienna, imperial and royal observatory, lat. + 48° 12′ 35″·5, long. 1h 5m 31s·5 E. On the university building an observatory was founded in 1756. Owing to the unsuitable locality and the want of instruments, very few observations of value were taken until the observatory was rebuilt in 1826, when some better instruments were procured, especially a meridian circle of 4-inches aperture, and a 6-inch refractor by Fraunhofer (mounted in 1832), used for observations of planets and comets. The *Annalen* commenced to appear in 1821; besides observations made at Vienna, they have contained Piazzi's original observations and Oeltzen's catalogue of stars between −15° and −31° decl. from Argelander's observations. From 1874 to 1879 a large and magnificent building (with four domes, the central one being 45 feet in diameter) was erected at Währing, north-west of the city, lat. + 48° 13′ 55″·4, long. 1h 5m 21s·5 E. In addition to the old instruments, two equatorial refractors were erected, one by Clark of 11¾-inches aperture, another by Grubb of 27-inches aperture (mounted 1883).

Vienna (Josephstadt), private observatory of Th. von Oppolzer, lat. + 48° 12′ 59″·4, long. 1h 5m 25s·3 E. Established in 1865; 6-inch refractor by Merz, 4-inch meridian circle.

Prague, university observatory, lat. + 50° 5′ 15″·8, long. 0h 57m 41s·4 E. Founded in 1751 in the Collegium Clementinum, in a high tower. Very few astronomical observations have been taken here; at present only magnetic and meteorological work is attended to, as a 6-inch refractor by Steinheil and a 4-inch meridian circle cannot be mounted for want of a proper locality.

Senftenberg, in the east of Bohemia, lat. + 50° 5′ 55″, long. 1h 5m 52s E. Baron von Senftenberg's observatory; established in 1844. Observations of comets and planets made with small instruments till the owner's death (1858).

Gratz, lat. + 49° 35′ 45″, long. 1h 6m 0s E. Herr von Unkrechtsberg's observatory: 5-inch refractor by Merz. Julius Schmidt observed planets and comets from 1852 to 1858.

Kremsmünster, Upper Austria, lat. + 48° 3′ 23″·8, long. 0h 56m 32s·2 E. Founded in 1748 at the gymnasium of the Benedictines. 3-inch meridian circle (mounted in 1827), used for observing minor planets; 5½-inch refractor (mounted in 1856), used for comets and minor planets.

Pola, seaport, Austria, naval observatory, lat. + 44° 51′ 49″, long. 0h 55m 23s·5 E. Founded in 1871; meridian circle of 6-inches aperture by Simms, 6-inch refractor by Steinheil, magnetic and meteorological instruments. Twenty-eight minor planets were discovered here from 1874 to 1880 by J. Palisa.

Cracow, university observatory, lat. + 50° 3′ 50″·0, long. 1h 19m 51s·1 E. Possesses only small instruments.

Buda-pest (Ofen), royal observatory. Founded 1777; a new building was erected in 1813, and new instruments (a 6-inch refractor by Fraunhofer and a meridian circle by Reichenbach) provided, with which comets and planets were observed. Nothing has been heard of this observatory for the last fifty years.

O'Gyalla (near Komorn, Hungary), lat. + 47° 52′ 43″·4, long. 1h 12m 45s·6 E. Nicolas de Konkoly's observatory. Established in 1871, rebuilt and enlarged in 1876, devoted to spectroscopy and physical astronomy generally; there is a large workshop attached. A 10-inch silvered glass reflector by Browning was in use up to 1881, when it was disposed of and a 10-inch equatorial refractor (O.G. by Merz) mounted in its place; also a 6-inch refractor by Merz, and many spectroscopes and minor instruments. Results are published in 4to volumes.

Kalocsa (south of Buda-pest), lat. + 46° 31′, long. 1h 15m ± E. Observatory of the Jesuit college, founded in 1878 by Cardinal Haynald; 7-inch refractor by Merz.

Herény (Vas, Hungary), lat. + 47° 16′ 37″, long. 1h 6m 24s·7 E. E. and A. von Gothard's observatory. Founded in 1881; 10-inch reflector by Browning.

Switzerland.

Zurich, lat. + 47° 22′ 40″·0, long. 0h 34m 13s·6 E. An observatory existed since 1759; handed over to the Polytechnic School in 1855; new building erected in 1863. A 6-inch refractor by Merz and Kern, two transit instruments, &c. Sun-spots are regularly observed, but the institution is chiefly devoted to educational purposes.

Neuchâtel, lat. + 46° 59′ 51″·0, long. 0h 27m 50s·2 E. Erected in 1858; meridian circle of 4½-inches aperture by Ertel.

Geneva, lat. + 46° 11′ 58″·8, long. 0h 24m 35s·5 E. Founded in 1773; a new building erected in 1830. The observatory has been the centre of the important geodetic operations carried on in Switzerland since 1861. A 10-inch refractor (O.G. by Merz) was presented by the director Plantamour in 1880.

Spain and Portugal.

Madrid, royal observatory, lat. + 40° 24′ 29″·7, long. 0h 14m 45s·4 W. Observations are made of comets, sun-spots, &c., with an equatorial by Merz.

Cadiz, naval observatory, at San Fernando, lat. + 36° 27′ 41″·5, long. 0h 24m 49s·5 W. Founded in 1797.

Lisbon, royal observatory, lat. + 38° 42′ 31″·3, long. 0h 36m 44s·7 W. A large refractor was mounted in 1863.

Coimbra, university observatory, lat. + 40° 12′ 25″·8, long. 0h 33m 34s·5 W. Founded 1792. An astronomical ephemeris has been published from 1804.

Italy.

Turin, university observatory, lat. + 45° 4′ 6″, long. 0h 30m 45s·4 E. Founded in 1759 by the Academy of Science; rebuilt in 1820 on a tower of the Palazzo Madama, where a meridian circle by Reichenbach of 4-inches aperture was mounted; handed over to the university in 1865.

Milan, originally observatory of Brera College, now royal observatory of Brera, lat. + 45° 27′ 59″·2, long. 0h 36m 46s·1 E. Founded in 1763. The publication of an annual ephemeris from 1775 to 1875 and important theoretical works absorbed most of the time of the directors Oriani and Carlini, and the instruments were rather insufficient. In 1875 an 8-inch refractor by Merz was mounted, with which Schiaparelli has made valuable observations of Mars. An 18-inch refractor has been ordered from Merz.

Padua, university observatory, lat. + 45° 24′ 2″·5, long. 0h 47m 28s·6 E. Founded in 1761. In 1837 a meridian circle by Starke of 4-inches aperture was mounted, with which stars from Bessel's zones were re-observed; the results were published in five

catalogues. A 4½-inch refractor by Merz and Starke (1858) has served to observe comets, spectra of solar prominences, &c.

Gallarate, near Lago Maggiore, from 1860 to 1879, Baron Dembowski's observatory. From 1852 to 1859 Baron Dembowski had observed double stars at Naples with a 5-inch dialyte by Plössl, and a small transit circle by Starke. From 1860 he used a 7-inch refractor by Merz.

Modena, university observatory, lat. + 44° 38' 52"·8, long. 0h 43m 42s·8 E. Founded in 1819. There is a meridian circle by Reichenbach, but very little astronomical work has been done.

Bologna, university observatory, lat. + 44° 29' 47"·0, long. 0h 45m 24s·5 E. Founded in 1724 on a tower of the university building. Ephemerides were published from 1715 to 1836, but observations have only been made occasionally. A 3½-inch meridian circle was mounted in 1846.

Florence. In 1774 a museum of science and natural history was established, part of which was used as an observatory, lat. + 43° 46' 4"·1, long. 0h 45m 1s·5 E. Very few observations were made; only Donati's discoveries of six comets and his early observations of star-spectra deserve to be noticed. A new observatory was finished in 1872 at Arcetri, but is very badly built, so that two fine refractors by Amici of 11- and 9½-inches aperture (the mountings unfinished) can only find limited application.

Rome, observatory of the Roman College, lat. + 41° 53' 53"·7, long. 0h 49m 54s·7 E. Established in 1787. Little was done until De Vico became director in 1838, when numerous observations of satellites, comets, &c., were commenced with a 6¼-inch refractor by Cauchoix. In 1853 a new observatory was erected on the unfinished piles of the church of St Ignatius, and furnished with a 9-inch refractor by Merz, a meridian circle by Ertel of 3½-inches aperture (in use from 1842), a 3-inch refractor for observing sun-spots, &c. With these instruments, to which were later added powerful spectroscopes, Secchi has made a great many observations, chiefly relating to spectrum analysis and physical astronomy.

Rome, observatory of the Capitol, lat. + 41° 53' 33"·6. Established in 1848; belongs to the university; small transit circle and a 4½-inch refractor by Merz. The latter is used by Respighi for observations of solar prominences.

Naples, royal observatory, situated at Capo di Monte, lat. + 40° 51' 45"·4, long. 0h 57m 0s·9 E. Erected in 1812-19 (an observatory commenced in 1790 at the Royal Museum had been left unfinished); furnished with a number of instruments, among which a 4-inch meridian circle and two repeating circles by Reichenbach, a 6½-inch equatorial by Reichenbach and Fraunhofer, &c. Very little was done until De Gasparis entered the observatory, where he has discovered nine minor planets and made other observations, partly with a 6-inch Merz refractor.

Palermo, royal observatory, lat. + 38° 6' 44", long. 0h 53m 25s·0 E. Erected in 1790 on a tower of the royal palace. The principal instruments were a reversible vertical circle by Ramsden of 5-feet diameter, with a 3-inch telescope, and a transit instrument of 3-inches aperture. With these Piazzi observed the stars contained in his celebrated *Catalogue of 7641 Stars* (1814); this work led him to the discovery of the first minor planet, Ceres, on 1st January 1801. The activity was revived in 1857, when a meridian circle by Pistor and Martins of 5-inches aperture was mounted and a 9½-inch refractor ordered from Merz. The latter has been used by Tacchini for spectroscopic work, chiefly on the sun.

Etna. In 1879-80 an observatory was built at the "Casa degl' Inglesi," 9650 feet above the sea. During the summer months a 12 inch object-glass by Merz is to be used here for solar observations, while there is to be a duplicate mounting for it at Catania for use during the winter.

GREECE.

Athens, lat. + 37° 58' 20", long. 1h 34m 55s·7 E. Commenced in 1845; founded by Baron Sina. There is a refractor of 6½-inches aperture, which has been used by Julius Schmidt (died 1884) for observations of the physical appearance of the moon, planets, and comets.

RUSSIA.

St Petersburg, observatory of the Academy of Sciences, lat. + 59° 56' 29"·7, long. 2h 1m 13s·5 E. Founded in 1725, restored in 1803; meridian circle by Ertel and other instruments. A small university observatory was founded in 1880.

Pulkowa, Nicholas Central Observatory, lat. + 59° 46' 18"·7, long. 2h 1m 18s·7 E. Finished in 1839. Was under the direction of F. G. W. Struve till 1861, since then of his son O. Struve; the staff consists now of the director, four astronomers, four assistants, two computers, and a secretary. The principal instruments are:—a transit instrument by Ertel of 6-inches aperture and 8½-feet focal length; a vertical circle by Ertel of 6-inches aperture and 6½-feet focal length (the circle of 3½-feet diameter has been redivided by Repsold),—these two instruments have been used for determining standard places of stars for the epochs 1845 and 1865; a meridian circle by Repsold (6-inches aperture, 4-feet circles), used since 1841 to observe all stars north of − 15° decl. down to the 6th mag., and all others observed by Bradley; a prime vertical transit by Repsold with 6¼-inches aperture, used for determining the constant of aberration; a 7½-inch heliometer by Merz, which has been very little used; an equatorial refractor by Merz of 22-feet focal length and 14·9-inches aperture (remounted by Repsold in 1880), which has been used incessantly by O. Struve since 1841 to observe double stars. A 30-inch refractor is now in process of construction, the object-glass being made by Clark, the mounting by Repsold. In addition to numerous memoirs and papers by the various astronomers, published by the Academy of St Petersburg, the *Pulkowa Observations* are published in large 4to volumes (10 vols. published up to 1883).

Abo (Finland), university observatory, lat. + 60° 26' 56"·8, long. 1h 29m 8s·3 E. Founded in 1819. With the meridian circle by Reichenbach of 4-inches aperture, Argelander observed the 560 stars (chiefly stars with proper motion) contained in the Abo catalogue. In consequence of a great fire in 1827 the university and observatory were moved to Helsingfors.

Helsingfors (Finland), university observatory, lat. + 60° 9' 43"·3, long. 1h 39m 49s·2 E. Erected in 1832-35; furnished with a 6½-inch refractor and the instruments from Abo, including a transit instrument by Fraunhofer of 5½-inches aperture. With the last-named instrument, furnished with a divided arc, Kruger has observed the stars between + 55° and + 65° decl.

Dorpat, university observatory, lat. + 58° 22' 47"·1, long. 1h 46m 53s·6 E. Founded in 1805; from 1814 under the direction of F. G. W. Struve. With a meridian circle by Reichenbach observations were made from 1822 to 1843 of 2874 stars, chiefly double stars (Struve's *Positiones mediæ*, 1852), while the 9½-inch refractor by Fraunhofer was used from 1824 to 1837 for measuring double stars (*Mensuræ micrometricæ*, 1837, also *Catalogus novus stellarum duplicium*, 1827). Dorpat was also the centre of important geodetic works. Mädler, who succeeded Struve in 1840, continued the observations of double stars. The meridian circle has been used since 1870 for observations of stars between + 70° and + 75° decl.

Vilna, lat. + 54° 41' 0", long. 1h 41m 11s·9 E. Founded in 1753. From time to time observations of planets have been made with a 6-inch refractor (Merz, 1835) and minor instruments. Of late years the observatory has been devoted to astronomical physics; a photo-heliograph has been in operation from 1869 to 1876.

Warsaw, university observatory, lat. + 52° 13' 5"·7, long. 1h 24m 7s·4 E. Erected in 1820-21; meridian circle by Reichenbach, 6-inch refractor by Merz.

Plonsk (Poland), Dr Jedrzejewicz's observatory, lat. + 52° 37' 3"·3, long. 1h 22m 4s E. Established in 1875; a 6½-inch refractor by Steinheil is being used for observations of double stars.

Moscow, university observatory, lat. + 55° 45' 19"·8, long. 2h 30m 17s·0 E. An observatory was built in 1825-32; the present building was erected about 1850. There is a 10·7-inch refractor by Merz (used for observations of planets and comets and spectroscopic observations of the sun), a meridian circle by Repsold of 5·3-inches aperture, &c. The *Annals*, published since 1874, contain many researches on the nature of comets by the director, Bredichin.

Kasan, university observatory, lat. + 55° 47' 24"·2, long. 3h 16m 23s·9 E. Founded in 1811, restored in 1842; 10-inch refractor by Merz, meridian circle by Repsold.

Kharkoff, lat. + 50° 0' 10"·2, long. 2h 24m 54s·7 E.

Kieff, university observatory, lat. + 50° 27' 11"·1, long. 2h 2m 0s·6 E. Erected in the years 1840-45; has a 9-inch refractor, a meridian circle, and smaller instruments.

Odessa, university observatory, lat. + 46° 28' 36"·2, long. 2h 3m 2s·4 E. Recently established; 5-inch refractor by Steinheil.

Nikolaieff, naval observatory, lat. + 46° 58' 20"·6, long. 2h 7m 54s·1 E. Erected in 1824; meridian circle by Ertel with 4-inches aperture, 9½-inch refractor by Repsold.

Tiflis. Founded in 1863 to assist the geodetic operations in the Caucasian provinces.

SWEDEN, NORWAY, AND DENMARK.

Stockholm, lat. + 59° 20' 33"·2, long. 1h 12m 14s·0 E., is under the Academy of Sciences. Founded in 1750; is best known by Wargentin's observations of Jupiter's satellites, carried on for many years. Meridian circle by Ertel of 4½-inches aperture, 7-inch equatorial refractor by Repsold; the latter is now being employed by Gyldén for researches on the annual parallax of bright stars.

Upsala, university observatory, lat. + 59° 51' 31"·5, long. 1h 10m 30s·6 E. Founded in 1730, but very little was done until the observatory acquired a 9-inch refractor by Steinheil, which has been used by the present director, Schultz, for micrometric observations of 500 nebulæ.

Lund, university observatory, lat. + 55° 41' 52"·0, long. 0h 52m 45s·0 E. Built in 1866 (an observatory had existed since about 1760, but only with very small instruments); 9½-inch equatorial refractor, object-glass by Merz, used for observations of double stars and minor planets; meridian circle by Repsold of 6¼-inches aperture, used for observing stars between + 35° and + 10° decl.

Christiania, university observatory, lat. + 59° 54' 43"·7, long.

$0^h\ 42^m\ 53^s{\cdot}6$ E. Erected in 1831; meridian circle by Ertel of 4-inches aperture, now used to observe stars between + 65° and + 70° decl.; a 4½-inch equatorial by Repsold, and a 7-inch refractor by Merz; magnetical instruments (which were extensively used by the first director, Hansteen).

Copenhagen, university observatory, lat. 55° 40′ 53″·0, long. $0^h\ 50^m\ 19^s{\cdot}8$ E. Founded in 1641 on the top of a high tower; the locality was so very unsuitable that Römer (the inventor of the transit instrument and modern equatorial, died 1710) established his own observatory at Vridlösemagle, at some distance from the city. The observatory on the tower was burned in 1728, restored in 1741 and 1780. A new observatory was erected in 1861, lat. +55° 41′ 13″·6, long. $0^h\ 50^m\ 19^s{\cdot}2$ E. It is furnished with an equatorial refractor by Merz of 11-inches aperture, with which D'Arrest made observations of 1900 nebulæ; a meridian circle by Pistor and Martins of 4½-inches aperture, with which Schjellerup observed 10,000 stars between +15° and −15° decl.; and a meridian transit instrument of 6½-inches aperture, intended for zone observations of very faint stars.

Holland and Belgium.

Leyden, university observatory, lat. + 52° 9′ 20″·3, long. $0^h\ 17^m\ 56^s{\cdot}2$ E. Founded already in 1632, but the instruments were always very small, and hardly any observations were taken until Kaiser became director in 1837. A 6-inch refractor by Merz was now provided, and in 1858-60 a new observatory was erected, and furnished with a 7-inch refractor by Merz and a meridian circle by Pistor and Martins of 6·3-inches aperture. These instruments have since been in constant use, the refractor for measures with a double-image micrometer, the meridian circle principally for observations of stars between + 30° and + 35° decl., and of southern standard stars. There is a large collection of minor instruments and apparatuses for special researches. *Annalen der Sternwarte in Leyden* appear in 4to volumes.

Utrecht, university observatory, lat. + 52° 5′ 10″·5, long. $0^h\ 20^m\ 31^s{\cdot}7$ E. Seems to have existed already during the 18th century; a new building was erected in 1855, but there are only small instruments, except a 10-inch object-glass by Steinheil on Gauss's plan, which seems to be a failure.

Brussels, royal observatory, lat. + 50° 51′ 10″·7, long. $0^h\ 17^m\ 28^s{\cdot}6$ E. Erected in 1829-34. A transit instrument by Gambey and a mural circle by Troughton have been used for observations of stars having proper motion, but the institution was while under the direction of Quetelet chiefly devoted to physics and meteorology. In 1877 a 6-inch refractor by Merz was mounted, and a meridian circle by Repsold and a 15-inch refractor by Cooke have been mounted in a temporary manner, pending the erection of a new observatory at some distance from the city. The *Annales de l'Observatoire de Bruxelles* (28 vols. 4to) contain, besides the observations, many investigations on special subjects.

United States.

Albany (New York), Dudley Observatory, lat. + 42° 39′ 49″·5, long. $4^h\ 54^m\ 59^s{\cdot}2$ W. Erected in 1851-56 by subscription; equatorial refractor by Fitz of 13-inches aperture, meridian circle by Pistor and Martins of 8-inches aperture, now used for observing stars between + 1° and + 5° decl., transit instrument of 6·4-inches aperture by the same makers.

Allegheny (Pennsylvania), lat. + 40° 27′ 41″·6, long. $5^h 20^m\ 2^s{\cdot}9$ W. Founded in 1860 in connexion with the university; 13-inch equatorial refractor by Fitz (improved by Clark), mounted in 1867; several spectroscopes and other instruments for researches on solar energy.

Amherst (Massachusetts), lat. +42° 22′ 15″·6, long. $4^h 50^m\ 7^s{\cdot}3$ W. Founded in 1857 as an annex to the college; 7¼-inch refractor by Clark.

Annapolis (Maryland), lat. + 38° 58′ 53″·5, long. $5^h\ 5^m\ 56^s{\cdot}5$ W. U.S. Naval Academy observatory, used for instruction only; 4-inch meridian circle by Repsold, 7¾-inch refractor by Clark, and smaller instruments.

Ann Arbor (Michigan), lat. +42° 16′ 48″·0, long. $5^h\ 34^m 55^s{\cdot}2$ W. Belongs to the university of Michigan; erected in 1854; meridian circle by Pistor and Martins of 6½-inches aperture, 12½-inch equatorial refractor by Fitz. The observatory is known by the works of the successive directors, Brunnow and Watson; the latter discovered twenty-one minor planets here.

Cambridge (Massachusetts), Harvard College observatory, lat. + 42° 22′ 48″·3, long. $4^h\ 44^m\ 31^s{\cdot}0$ W. Erected in 1839. Equatorial refractor of 15-inches aperture by Merz, with which W. C. Bond discovered a satellite of Saturn (Hyperion) in 1848, and which was afterwards used by G. P. Bond to observe the nebula of Orion,—it is now employed by Pickering for extensive photometric observations of fixed stars and satellites; a meridian circle by Troughton and Simms with 8¼-inches aperture, mounted in 1870, used for observations of standard stars and stars between + 50° and + 55° decl. The *Annals* of the observatory (13 vols. 4to) form one of the most important collections of astronomical researches. Since 1877 the means of the institution have been increased by public subscription, and a large staff of assistants has since been actively employed on photometric and meridian work.

Chicago (Illinois), Dearborn Observatory, lat. + 41° 50′ 1″·0, long. $5^h\ 50^m\ 26^s{\cdot}8$ W. Attached to the university; founded by subscription in 1862. The principal instrument is an 18½-inch equatorial refractor by Clark (*mounted in 1864, but not used till 1877*), with which Burnham has continued his *observations and discoveries* of double stars, commenced with a 6-inch refractor. There is also a 6-inch meridian circle by Repsold.

Cincinnati (Ohio), lat. + 39° 6′ 26″·5, long. $5^h\ 37^m\ 58^s{\cdot}9$ W. In 1842 an observatory was founded by subscription, and furnished with an equatorial refractor of 11¼-inches aperture by Merz. In 1873 the observatory was removed to a distance from the city, to Mount Lookout, lat. + 39° 8′ 35″·5, long. $5^h\ 37^m\ 41^s{\cdot}4$ W. The refractor has been almost exclusively devoted to observations of double stars (*Publications of the Cincinnati Observatory*, 5 parts, 8vo).

Clinton (New York), Litchfield Observatory of Hamilton College, lat. + 43° 3′ 17″·0, long. $5^h\ 1^m\ 37^s{\cdot}4$ W. Erected by subscription, 1852-55; equatorial refractor of 13½ inches by Spencer, employed by C. H. F. Peters for construction of celestial charts (Nos. 1-20 published in 1882), in the course of which work he has discovered forty-one minor planets.

Georgetown (District of Columbia), college observatory, lat. +38° 54′ 26″·2, long. $5^h\ 8^m\ 18^s{\cdot}3$ W. Erected in 1844; 6-inch refractor and small meridian circle, both by Simms.

Glasgow (Missouri), Morrison Observatory, lat. + 39° 16′ 16″·8, long. $6^h\ 11^m\ 18^s{\cdot}0$ W. Founded in 1876; attached to the university; 12¼-inch equatorial refractor by Clark, used for observations of comets, planets, and double stars; meridian circle by Simms of 6-inches aperture.

Hanover (New Hampshire), Dartmouth College observatory, lat. + 43° 42′ 15″, long. $4^h\ 49^m\ 8^s{\cdot}0$ W. Founded in 1853; 9½-inch equatorial by Clark, used by C. A. Young (up to 1878) for spectroscopic observations of the sun; meridian circle by Simms of 4-inches aperture.

Hastings (New York), Prof. Henry Draper's observatory, lat. + 40° 59′ 25″, long. $4^h\ 55^m\ 29^s{\cdot}7$ W. Built in 1860; 28-inch reflector by the owner, 11-inch refractor (with photographic lens) by Clark, both used up to the owner's death (1882) for celestial and spectrum photography. The first photograph of the nebula of Orion was taken here in 1880.

Madison (Wisconsin), Washburn Observatory, lat. + 43° 4′ 36″·7, long. $5^h\ 57^m\ 37^s{\cdot}9$ W. Erected at the expense of Governor Washburn in 1878; belongs to the university. Meridian circle by Repsold of 4·8-inches aperture, 15½-inch equatorial refractor by Clark, used for observations of nebulæ and double stars. *Publications* in 8vo volumes.

Mount Hamilton (California), Lick Observatory of the university of California, lat. + 37° 21′ 3″, long. $8^h\ 6^m\ 26^s{\cdot}7$ W., about 4250 feet above sea-level. Is being erected in pursuance of the will of the late James Lick, and is to contain a 36-inch refractor by Clark. The suitability of the site was tested in 1879 by Burnham, who observed for some weeks with his 6-inch refractor. A 12-inch refractor and a 5-inch photoheliograph were used for observing the transit of Venus in 1882.

New Haven (Connecticut), Winchester Observatory of Yale College, lat. + 41° 18′ 36″·5, long. $4^h\ 51^m\ 42^s{\cdot}2$ W. An observatory had existed since 1830, possessing among other instruments a 9-inch refractor by Clark and a meridian circle by Ertel. In 1880 a bureau for verifying chronometers and thermometers was established, and in 1881 the observatory was rebuilt, and furnished with a 6-inch heliometer by Repsold, and an 8-inch equatorial refractor by Grubb.

New York, L. M. Rutherfurd's observatory, lat. + 40° 43′ 48″·5, long. $4^h\ 55^m\ 56^s{\cdot}6$ W. 13-inch refractor by Rutherfurd and Fitz, used for celestial photography.

Northfield (Minnesota), Carleton College observatory, lat. + 44° 27′ 40″·8, long. $6^h\ 12^m\ 35^s{\cdot}9$ W. Erected in 1878; 8¼-inch refractor by Clark.

Princeton (New Jersey). Attached to the college are two observatories,—the "J. C. Green School of Science observatory," lat. + 40° 20′ 57″·8, long. $4^h\ 58^m\ 37^s{\cdot}6$ W., erected in 1877, and furnished with a 9½-inch refractor by Clark; and the Halsted observatory, in which a 23-inch refractor by Clark was mounted in 1883.

Rochester (New York), Warner Observatory, lat. + 43° 8′ 15″, long. $5^h\ 11^m\ 20^s$ W. Erected by H. H. Warner in 1879-80; has a 16-inch refractor by Clark.

Washington (D.C.), U.S. naval observatory, lat. + 38° 53′ 38″·8, long. $5^h\ 8^m\ 12^s{\cdot}1$ W. Observations were commenced in a temporary observatory in 1838; the naval observatory was organized in 1842; observations commenced in 1845. For some years a large amount of zone observations were taken with three meridian instruments, but as Maury, who held the office of superintendent from 1844 to 1861, devoted himself exclusively to meteorology, the astronomical work was considered of less importance. Since 1861 the observa-

tions have again been published in annual 4to volumes, the appendices to which contain many important memoirs by the five astronomers attached to the institution. In addition to these and the superintendent (a naval officer) there are three assistants. The instruments are:—a mural circle by Troughton and Simms of 4 inches; a transit instrument by Ertel of 5·3-inches aperture,—these two instruments have been used to observe a catalogue of 11,000 fixed stars; a 9·6-inch equatorial refractor by Merz, used for observing minor planets and comets; a meridian circle by Pistor and Martins of 8·5-inches aperture, mounted in 1865, and used for observing standard stars and planets; a 26-inch equatorial refractor by Clark, mounted in 1873, and used for observations of satellites and difficult double stars,—with this instrument Hall discovered the satellites of Mars in 1877. A new observatory is now being built, the former locality being too near the Potomac river.

Williamstown (Massachusetts), lat. + 42° 42′ 49″, long. $4^h\ 52^m\ 33^s$ 5 W. Founded in 1836; 7½-inch refractor by Clark; meridian circle of 4½-inches aperture by Repsold, mounted in 1882.

MEXICO.

Chapultepec (about 2 miles south-west of Mexico), national observatory, lat. + 19° 25′ 17″·5, long. $6^h\ 36^m\ 38^s$·2 W. Erected in 1877-80; a 15-inch equatorial refractor by Grubb was procured in 1882; there is also an altazimuth by Simms, &c. In 1883 the observatory was moved to Tacubaya.

SOUTH AMERICA.

Santiago (Chili), national observatory, lat. – 33° 26′ 42″·0, long. $4^h\ 42^m\ 42^s$·4 W. In 1849 the U.S. Government sent an astronomical expedition to Chili to observe Venus and Mars, in order to determine the solar parallax. When the expedition returned in 1852, the Government of Chili bought all the instruments—a 6-inch meridian circle by Pistor and Martins, a 6½-inch refractor by Fitz, &c. Meridian observations of southern stars, observations of Mars in opposition, of the parallax of α Centauri, &c., were carried on by Moesta till 1863 (from 1860 in a new observatory). Since the retirement of Moesta very little has been heard of the institution, although it soon after received a 9½-inch refractor by Merz and Repsold. Two volumes of *Observations* have been published.

Lima (Peru). In 1866 a meridian circle of 7-inches aperture and a 10½-inch refractor were procured from Eichens, but we are not aware of any astronomical work having been done at Lima.

Rio de Janeiro (Brazil), imperial observatory, lat. – 22° 54′ 23″·8, long. $2^h\ 52^m\ 41^s$·4 W. Founded in 1845; no work done until 1871. The principal instruments are a meridian circle by Dollond, an altazimuth, a 9½-inch refractor by Henry, &c. A *Bulletin* was commenced in 1881.

Cordova (Argentine Republic), national observatory, lat. – 31° 25′ 15″·4, long. $4^h\ 16^m\ 45^s$·1 W. Erected in 1871, under the direction of B. A. Gould, who has here constructed his *Uranometria Argentina*, an atlas of all the stars visible to the naked eye from the south pole to +10° decl., with their apparent magnitudes. With a meridian circle by Repsold of 5-inches aperture 105 000 zone observations of stars between – 23° and – 80° decl. have been made, while an 11-inch refractor by Fitz, with photographic object-glass, has been employed for taking photographs of southern star-clusters. The results are being published in 4to volumes.

AFRICA.

Cape of Good Hope, royal observatory, lat. – 33° 56′ 3″·4, long. $1^h\ 13^m\ 55^s$·0 E. Founded in 1820; erected in 1825-29, about 3½ miles from Cape Town. Observations were commenced by Fallows in 1829 with a transit instrument by Dollond of 5-inches aperture and a mural circle by Jones. After the death of Fallows (1831), T. Henderson observed from 1832-33, chiefly the moon and Mars for determining their parallaxes, and α Centauri for annual parallax. He was succeeded as "His Majesty's astronomer" by Thomas Maclear, who undertook to verify and extend the arc of meridian measured by Lacaille in 1751-53, which work occupied the observatory staff for a number of years. The results of the meridian observations were therefore first published by Maclear's successors in the form of three star catalogues for 1840, 1850, and 1860. In 1849 a 7-inch equatorial refractor by Merz was mounted, and in 1855 a new meridian circle, a facsimile of the one at Greenwich, superseded the older instruments. With the equatorial comets, occultations of stars, &c., were observed. Maclear was succeeded by E. J. Stone (1870 to 1879), who, in addition to bringing out much of his predecessor's work, devoted himself and the staff to observations of stars, embodied in a catalogue of 12,441 stars for the epoch 1880. Under the present astronomer, D. Gill, standard stars between the equator and – 23° decl., as also stars suitable for investigations on refraction, are observed, while a 4-inch heliometer by Repsold is privately employed by the astronomer for researches on annual parallax.

Besides the observatory of *Lacaille* in Cape Town, already mentioned (lat. – 33° 55′ 16″·1, long. $1^h\ 13^m\ 41^s$ E.), another temporary observatory, at Feldhausen, lat. – 33° 58′ 56″·6, long $1^h\ 13^m\ 51^s$ E., 6 miles from Cape Town, deserves to be mentioned. It was here that Sir John Herschel observed nebulæ and double stars from 1834 to 1838 with a reflector of 18¼-inches aperture; the results were published in a large 4to volume in 1847.

Durban (Natal). Erected in 1882; 8-inch equatorial refractor by Grubb.

Algiers (Algeria), national observatory, lat. + 36° 45′ 2″·7, long. $0^h\ 12^m\ 11^s$·4 E. Recently founded.

St Helena, lat. – 15° 55′ 26″·0, long. $0^h\ 22^m\ 54^s$·6 W. Erected in 1829, with a transit instrument and mural circle; M. Johnson observed the places of 606 southern stars from 1829 to 1833.

INDIA.

Madras, Government observatory, lat. + 13° 4′ 8″·1, long. $5^h\ 20^m\ 59^s$·4 E. In operation since the beginning of this century. In 1831 a transit instrument and a mural circle, both of 3¾-inches aperture, by Dollond were mounted, and with these T. G. Taylor observed 11,000 stars, published in a large *Catalogue* (1845); a *Subsidiary Catalogue* of 1440 stars appeared in 1854. Taylor's successor, Jacob, chiefly devoted himself to double stars. A meridian circle by Simms was mounted in 1858, and in 1865 an 8-inch equatorial refractor, also by Simms, was put up, and the observations have been vigorously continued under the direction of Pogson. Eight volumes in 4to of *Observations* were published from 1832 to 1854. In a small private observatory at Madras, E. B. Powell observed double stars with a 4-inch refractor by Simms from 1853.

Lucknow. An observatory was founded by the king of Oude, and observations were made with a transit instrument and mural circle by Major Wilcox from 1841 till his death in 1848. Both instruments and manuscripts were destroyed during the mutiny in 1857.

Trivandrum, lat. + 8° 30′ 32″, long. $5^h\ 7^m\ 59^s$ E. Founded by the rajah of Travancore in 1836, and furnished with a 5-inch refractor and a transit instrument by Dollond, and two mural circles by Jones and Simms. The building was badly constructed, and the instruments could not be properly placed, so that no astronomical work could be done, but valuable magnetical and meteorological observations were made by J. A. Broun from 1852 to 1863.

CHINA.

Peking. The Jesuit missionaries under Verbiest erected in 1673 new instruments in the old observatory built in 1279 by Ko Show King. Observations were made and published at least up to 1770. The Russian embassy now maintains a meteorological observatory at Peking.

Hong Kong. In 1883 the colonial Government established an observatory, furnished with a 6-inch refractor, a small transit instrument, and full equipment of magnetical and meteorological instruments.

TURKESTAN.

Tashkend. Founded in 1874 to assist in the geodetic operations of the Russian general staff; 6-inch refractor and meridian circle by Repsold.

AUSTRALIA.

Paramatta (New South Wales), lat. – 33° 48′ 50″, long. $10^h\ 4^m\ 6^s$·3 E. Erected by Sir Thomas Macdougall Brisbane, in 1821; handed over to the New South Wales Government in 1826; furnished with a transit instrument and a mural circle by Troughton, with which observations of southern stars were made by C. Rumker and Dunlop in the years 1822 to 1826, and from which a catalogue of 7385 stars was deduced (1835). The value of this catalogue is, however, lessened by instrumental imperfections. Observations were also made of comets, double stars, and nebulæ. From about 1835 no observations seem to have been made; the observatory was abolished in 1855.

Sydney (New South Wales), lat. – 33° 51′ 41″·1, long. $10^h\ 4^m\ 50^s$·6 E. Founded in 1855; furnished with the instruments from Paramatta, and a very inferior meridian circle by Jones (improved by Simms). In 1861 a 7¼-inch refractor by Merz, and in 1874 an 11½-inch equatorial refractor by Schroder were mounted, and have been regularly used for observations of double stars. In 1879 a meridian circle by Simms of 6-inches aperture was acquired.

Windsor (New South Wales), lat. – 33° 36′ 28″·9, long. $10^h\ 3^m\ 21^s$·7 E. Private observatory of Mr J. Tebbutt, who has devoted himself since 1861 to discoveries and observations of comets, using a 4½-inch refractor by Cooke.

Melbourne (Victoria), lat. – 37° 52′ 7″·2, long. $9^h\ 39^m\ 38^s$·8 E. Founded in 1853 at Williamstown. In 1861 a meridian circle by Simms of 5-inches aperture was mounted, but in 1863 the observatory was moved to Melbourne, lat. – 37° 49′ 53″·4, long. $9^h\ 39^m\ 54^s$ 8 E. The instrumental equipment was further increased by "the great Melbourne telescope," a Cassegrain reflector, equatorially mounted, of 4-feet aperture and 20-feet focal length, made by Th. Grubb and erected in 1869, since when it has been used for observations of nebulæ and lunar photography; there is also an 8-inch refractor by Cooke, used for observations of comets, &c. The results of the meridian work from 1861 to 1875 are published in five 8vo volumes,

and a *First Melbourne Catalogue* of 1227 stars was published in 1874.

Adelaide (South Australia), lat. $-34° 55' 33''\cdot5$, long. $9^h 14^m 21^s\cdot3$ E. In operation since 1861: has been gradually improved, and contains now an 8-inch equatorial by Cooke, and a transit circle has been ordered. (J. L. E. D.)

INDEX OF OBSERVATORIES.

OBSIDIAN, a volcanic glass, said to have been named after its discoverer Obsidius. It is usually of black, brown, or grey colour, and in some varieties banded or striated. The colour is generally due not so much to the vitreous mass itself as to the presence of minute foreign bodies or microlites, which in some cases appear to be incipient crystals of felspar, while in others they probably consist of such minerals as augite, hornblende, biotite, and magnetite. These microscopic enclosures are occasionally arranged in curved lines, producing beautiful examples of fluidal structure (see GEOLOGY, vol. x. p. 230, fig. 2). Spherulites are not uncommon in obsidian, and are sometimes sufficiently large to impart a distinctly globular structure to the stone. Other varieties are rich in microscopic pores, or may even present to the naked eye a vesicular texture. It is notable that certain kinds of obsidian possess a peculiar metallic sheen, which has been attributed by Professor Zirkel to the presence of minute ovoid enclosures, and not to a porous structure, as had been previously suspected. There can be no doubt that obsidian has been formed by the rapid cooling of a felspathic lava. It is found chiefly in Iceland, the Lipari Islands, Melos and other isles of the Greek archipelago, the Caucasus, Siberia, Mexico, Peru, and New Zealand.

Obsidian breaks with a beautifully conchoidal fracture, yielding sharp-edged fragments, which have been largely used in various parts of the world as arrow-points, spear-heads, and rude knives. For these purposes it was extensively employed, under the name of *itzli*, by the ancient Mexicans, who quarried it at the Cerro de las Navajas, or "Hill of Knives," near the head-waters of the Great Barauca. Obsidian has also been used as a mirror,—a purpose for which its strong lustre has recommended it. By the ancient Greeks and Romans it was worked as a gem-stone; and, in consequence of its having been often imitated in black glass, there arose among collectors of gems in the last century the curious practice of calling all antique pastes "obsidians." Even at the present day the bottle-green varieties of obsidian are occasionally cut and polished as ornamental stones. They bear some resemblance to peridotes and tourmalines, but are deficient in hardness.

OCCAM, WILLIAM OF (d. *c.* 1349), the great English schoolman (*Doctor invincibilis*), was born in the village of Ockham in the county of Surrey in the end of the 13th century. Scarcely any traces of his early life remain. Unattested tradition says that the Franciscans persuaded him while yet a boy to enter their order, sent him to Oxford to Merton College, and to Paris, where he was first the pupil, then the successful rival, of the celebrated John Duns Scotus. He was at the height of his fame as a lecturer in the university of Paris when the famous quarrel arose between Philip the Fair and Pope Boniface VIII., but it does not appear that he took any part in the strife.[1] He probably left France about 1314, and there are obscure traces of his presence in Germany, in Italy, and in England during the following seven years. We only know that in 1322 he appeared as the provincial of England at the celebrated assembly of the Franciscan order at Perugia, and that there he headed the revolt of the Franciscans against Pope John XXII. His share in this revolt and his writings to justify his position gave rise to his trial for heresy before the bishops of Ferrara and Bologna, which resulted in his imprisonment for seventeen weeks in the dungeons of the papal palace at Avignon. He and his companions—Michael of Cesena, general of the order, and Bonagratia—managed to escape, and found their way to Munich, where they formed the most conspicuous members of that band of Franciscans who aided Louis of Bavaria in his long contest with the papal curia. "Defend me with the sword and I will defend you with the pen," was Occam's proposal to Louis; and from their haven of refuge at Munich the recusant Franciscans sent forth books and pamphlets refuting the extravagant pretensions of papal authority. Michael of Cesena died in 1342, and Occam, who had received from him the official seal of the order, was recognized as general by his party. The date of his death and the place of his burial are both uncertain. He probably died at Munich in 1349, and was buried in the graveyard of the Franciscan convent. Some writers assert that he was reconciled to Rome, and in proof of submission sent the official seal to William Farinerius, who had been appointed general of the order by the pope; others declare that, like Cesena and Bonagratia, he died excommunicate.

William of Occam was the most prominent intellectual leader in an age which witnessed the disintegration of the

[1] The famous *Disputatio super Potestate Prælatis Ecclesiæ, atque Principibus Terrarum commissa*, which belongs to this controversy, and has been commonly attributed to Occam, was probably written by Peter Dubois, a Parisian lawyer.

old scholastic realism, the rise of the theological scepticism of the later Middle Ages, the great contest between pope and emperor which laid the foundations of modern theories of government, and the quarrel between the Roman curia and the Franciscans which showed the long-concealed antagonism between the theories of Hildebrand and Francis of Assisi; and he shared in all these movements.

The common account of his philosophical position, that he reintroduced nominalism, which had been in decadence since the days of Roscellinus and Abelard, by teaching that universals were only *flatus vocis*, is scarcely correct. The expression is nowhere found in his writings. He revived nominalism by collecting and uniting isolated opinions upon the meaning of universals into a compact system, and popularized his views by associating them with the logical principles which were in his day commonly taught in the universities. He linked the doctrines of nominalism on to the principles of the logic of Psellus, which had been introduced into the West in the *Summulæ* of Peter of Spain, and made them intelligible to common understandings. His philosophical teaching contains little that was new; and all the details of nominalism had been taught by writers who preceded him. The problem of mediæval philosophy, however differently stated, was the same question which faces modern thinkers. How comes it that things which are seen as separate individual objects can be thought of in classes, and so science created? What underlies the possibility of using common nouns when everything apprehended by the senses is a separate subsisting phenomenon? Realism solved the problem by supposing something *in rerum natura* which actually corresponded to the class, and whose proper name was the common noun; nominalism explained that the logical faculties of the mind grouped individuals by its own powers, and that universals were creations of the mind which thought. The three chief positions in the nominalist solution of the possibility of a common knowledge were all the common property of scholastic thinkers before Occam's day. It had been currently taught (by Ægidius and by Antonius Andreas) that the principal use of universals, whatever they were in themselves, was to serve as logical predicates, and in this way bring a variety of subjects together, or, in other words, group individual things in a class. Many of the schoolmen (Walter Burleigh, Durandus, &c.) declared that this logical function of universals was the one thing about them that deserved notice and constituted their essential nature. Durandus and others had asserted that all that universals did was in this logical fashion to bring together several individual objects in such a way that they could be denoted by the same common term. These propositions really exhaust the essential doctrines of nominalism, and they were all stated and were the common property of scholastic philosophy before Occam's time. What he did was to make nominalism simpler by introducing a way of putting the theory suggested by the Byzantine logic. Psellus and his followers explained many difficulties in logic by showing that in speech words were used like the figures of arithmetic or the signs of algebra. There is no reason why x should mean four sheep except the will of the algebraist who starts with that assumption. In the same way, there is no reason why the word "triangle" should stand for the thought it expresses, or the thought for the infinitude of individual triangles; but by *suppositio* the one is used for the other, and we can reason with word or thought just as the algebraist can do with his signs. Universals, said Occam, bore the same relation to the infinite number of individuals that signs do to the things signified. The universal, be it a thought or a word, is nothing but a sign which by *suppositio* is beforehand taken to denote a number of individual things, and is thus the common noun denoting them all.

This way of explaining community of knowledge and of defending nominalism went a good deal deeper, and became a theory of knowledge which led Occam into what was called theological scepticism. Most of the adherents of the mystical schools of the Middle Ages held that the doctrines of the church were isolated truths, each of which was to be received by a species of enthusiastic intuition, and were incapable either of systematic arrangement in a body of divinity or of being intelligibly comprehended by the mind. Before Occam appeared, mystics taught a theory of theological scepticism which declared that the truths of the Christian faith were to be taken on trust, although the reason might find logical flaws in each one of them. Occam made this theological scepticism almost a commonplace by basing it on his theory of knowledge. All knowledge, he taught, contained a double inadequacy, which arose from the needs of thinking and of expressing thought in language. Words were but signs, inadequate representations of the thoughts they stood for, and the thoughts themselves were inadequate symbols used by *suppositio* instead of the individual objects which they represented. The real individual thing was apprehended by a *vis intuitiva*, in sense, vision, or touch, &c., but, when the mind begins to think or to argue, error may creep in, for thoughts are inadequate expressions, stereotyped aspects, and words are only signs of signs. Theological knowledge is like all other knowledge, theological argumentation has the inadequacy that belongs to every process of thought. The *Centilogium Theologicum* usually appended to Occam's *Commentary on the Sentences* of Peter the Lombard contains a consistent application of this theory of knowledge to theological dogmas, every one of which is shown to be irrational, but at the same time true in the vision of faith. The most interesting application of his method, however, is to be found in the *Tractatus de Sacramento Altaris*, in which, while accepting as a matter of faith the mediæval doctrine of the real presence, Occam shows that a much more rational theory might be propounded, and actually sets forth a theory of the Eucharist which was afterwards adopted almost verbatim by Luther, and which is now known as consubstantiation.

Occam was best known during his lifetime and in the succeeding centuries for the part he took in the prolonged contest between Louis of Bavaria and the papal curia. Louis had been legally elected emperor of Germany, but the pope, who claimed that his power to crown gave him the right to veto any election, refused to acknowledge Louis, and espoused the cause of his rival. The contest was prolonged during more than a quarter of a century, and its interest lies chiefly in the writings of a group of men who, sheltered at Munich, published their views on the relations between civil and religious authority, and on the rights of nations. The most remarkable of the many publications which this controversy called forth was undoubtedly the *Defensor Pacis* of Marsilius of Padua, which appeared in 1324 or 1326, and which was the prediction of the modern, as Dante's *De Monarchia* (1311-13) was the epitaph of the mediæval state. Occam published several treatises in which, while he confines himself more to the details of the controversy going on before him, there are evident traces of sympathy with the opinions of Marsilius. Pope Clement VI. has left on record that Marsilius "was taught his errors by and got them from" William of Occam; if this be true, the Italian jurist must have had private intercourse with the great English schoolman, for all Occam's genuine writings on the controversy appeared after the *Defensor Pacis*. In the *Opus nonaginta dierum* (1330-33), and in its successors, the *Tractatus de dogmatibus Johannis XXII. papæ* (1333-34), the *Compendium errorum Johannis XXII. papæ* (1335-38),

and in the *Defensorium contra errores Johannis XXII. papæ* (1335-39), Occam only incidentally expounds his views as a publicist; the books are mainly, some of them entirely, theological, but they served the purpose of the emperor and of his party, because they cut at the root of the spiritual as well as of the temporal supremacy of the pope. In his writing *Super potestate summi pontificis octo quæstionum decisiones* (1339-42) Occam attacks the temporal supremacy of the pope, insists on the independence of kingly authority, which he maintains is as much an ordinance of God as is spiritual rule, and discusses what is meant by the state. His views on the independence of civil rule were even more decidedly expressed in the *Tractatus de jurisdictione imperatoris in causis matrimonialibus*, in which, in spite of the mediæval idea that matrimony is a sacrament, he demands that it belongs to the civil power to decide cases of affinity and to state the prohibited degrees. His last work, *De Electione Caroli VI.*, restates his opinions upon temporal authority and adds little that is new.

In all his writings against Pope John XXII. Occam inveighs against the pope's opinions and decisions on the value of the life of poverty in the practice of religion. The *Compendium errorum* selects four papal constitutions which involved a declaration against evangelical poverty, and insists that they are full of heresy. Occam was a sincere Franciscan, and believed with his master that salvation was won through rigid imitation of Jesus in His poverty and obedience, and up to his days it had always been possible for Franciscans to follow the rules of their founder within his order. But Pope John XXII. took advantage of a dispute between the more zealous Franciscans and others who had departed from the strict rule of their founder to condemn the doctrine of evangelical poverty, and to excommunicate those who held it. This made many Franciscans question whether, when the pope set his opinion against that of Francis their founder, the pope could be infallible; and some of them were so convinced of the necessity of evangelical poverty for a truly Christian life that they denounced the pope when he refused them leave to practise it as Antichrist, or the being who stood between Christians and the means of holy living. After Occam's days the opinions of Francis prevailed in many quarters, but the genuine Franciscans had no place within the church. They were Fraticelli, Beghards, Lollards, or other confraternities unrecognized by the church, and in steady opposition to her government.

There is no good monograph on Occam. For an account of his logic, see Prantl, *Geschichte der Logik* (1855-70); for his philosophy, see Stöckl, *Geschichte der Philosophie des Mittelalters* (1864-66), vol. ii.; for his publicist writings, see Riezler, *Die literarischen Widersacher der Papste zur Zeit Ludwig des Baiers* (1874). See also Lindsay's article on "Occam and his connexion with the Reformation," in the *Brit. Quart. Review*, July 1872. (T. M. L.)

OCEAN. See SEA.

OCEANIA. See POLYNESIA.

OCELOT. The smaller spotted or striped species of the genus *Felis* (see MAMMALIA, vol. xv. p. 435), of both the Old and the New World, are commonly called tiger-cats. Of these, one of the best-known and beautifully marked forms, peculiar to the American continent, has received the name of Ocelot (*Felis pardalis*), though zoologists are still undecided whether under this designation several distinct species have not been included, or whether all the ocelots are to be referred to a single species showing great individual or racial variation. Their fur has always a tawny yellow or reddish-grey ground colour, and is marked with black spots, aggregated in streaks and blotches, or in elongated rings enclosing an area which is rather darker than the general ground colour. They range through the wooded parts of tropical America, from Arkansas in the north as far south as Paraguay, and in their habits resemble the

Ocelot.

other smaller members of the cat tribe, being ready climbers and exceedingly bloodthirsty.

OCHINO, BERNARDINO (1487-1564), Italian Reformer, was born at Siena in 1487. At an early age he entered the order of Observantine Friars, and rose to be its general, but, craving a stricter rule, transferred himself in 1534 to the newly-founded order of Capuchins. He had already become famous for zeal and eloquence, and was the intimate friend of the noble Spaniard Juan de Valdès, of Bembo, Vittoria Colonna, Pietro Martire, Carnesecchi, and others destined to incur the suspicion of heresy, either from the moderation of their characters or from the evangelical tincture of their theology. In 1538 he was elected vicar-general of his order; in 1539, urged by Bembo, he visited Venice and delivered a remarkable course of sermons, showing a decided tendency to the doctrine of justification by faith, which appears still more evidently in his dialogues published the same year. He was suspected and denounced, but nothing ensued until the establishment of the Inquisition in Rome in June 1542, at the instigation of the austere zealot Caraffa. Ochino almost immediately received a citation to Rome, and set out to obey it about the middle of August. According to his own statement, he was deterred from presenting himself at Rome by the warnings of Cardinal Contarini, whom he found at Bologna, dying of poison administered by the reactionary party. He turned aside to Florence, and after some hesitation escaped across the Alps to Geneva. He was cordially received by Calvin, and published within two years several volumes of *Prediche*, controversial tracts rather than sermons, explaining and vindicating his change of religion. He also addressed replies to Vittoria Colonna, Tolomei, and other Italian sympathizers who were reluctant to go to the same length as himself. His own breach with the Roman Church was decisive and irreparable, and illustrated the justice of Luther's description of justification by faith alone as the *articulus stantis vel cadentis ecclesiæ*, the vital point whose acceptance or rejection drew everything else along with it. In 1545 he became minister of the Italian Protestant congregation at Augsburg, which he was compelled to forsake when, in January 1547, the city was occupied by the imperial forces. He found an asylum in England, where he was made a prebendary of Canterbury, received a pension from Edward VI.'s privy purse, and composed his capital work, the *Tragedy*. This remarkable performance, originally written in Latin, is extant only in the translation

of Bishop Ponet, a splendid specimen of nervous English. The conception is highly dramatic; the form is that of a series of dialogues. Lucifer, enraged at the spread of Christ's kingdom, convokes the fiends in council, and resolves to set up the pope as Antichrist. The state, represented by the emperor Phocas, is persuaded to connive at the pope's assumption of spiritual authority; the other churches are intimidated into acquiescence; Lucifer's projects seem fully accomplished, when Heaven raises up Henry VIII. and his son for their overthrow. The conception bears a remarkable resemblance to that of *Paradise Lost*; and it is nearly certain that Milton, whose sympathies with the Italian Reformation were so strong, must have been acquainted with it. Several of Ochino's *Prediche* were also translated into English by a lady, Anna Cook, afterwards wife of Sir Nicholas Bacon; and he published numerous controversial treatises on the Continent. In 1553 the accession of Mary drove him from England. He became pastor of the Italian congregation at Zurich, composed principally of refugees from Locarno, and continued to write books which, repeating the history of his early works, gave increasing evidence of his alienation from the strict orthodoxy around him. The most important of these was the *Labyrinth*, a discussion of the freedom of the will, covertly assailing the Calvinistic doctrine of predestination. In 1563 the long-gathering storm of obloquy burst upon the occasion of the publication of his *Thirty Dialogues*, in one of which his adversaries maintained that he had justified polygamy under colour of a pretended refutation. His dialogues on divorce and the Trinity were also obnoxious. No explanation was allowed. Ochino was banished from Zurich, and, after being refused a shelter by other Protestant cities, directed his steps towards Poland, at that time the most tolerant state in Europe. He had not resided there long when an edict appeared banishing all foreign dissidents. Flying from the country, he encountered the plague at Pinczoff; three of his four children were carried off; and he himself, worn out by misfortune, expired in solitude and obscurity at Schlakau in Moravia, about the end of 1564. His reputation among Protestants was at the time so bad that he was charged with the authorship of the treatise *De tribus Impostoribus*, as well as with having carried his alleged approval of polygamy into practice. It was reserved for his recent biographer Dr Benrath to justify him, and to represent him as a fervent evangelist and at the same time as a speculative thinker with a passion for free inquiry, always learning and unlearning and arguing out difficult questions with himself in his dialogues, frequently without attaining to any absolute conviction. The general tendency of his mind, nevertheless, was counter to tradition, and he is remarkable as resuming in his individual history all the phases of Protestant theology from Luther to Socinus. He is especially interesting to Englishmen for his residence in England, and the probable influence of more than one of his writings upon Milton.

All attainable information respecting Ochino is collected in Dr Benrath's excellent German biography, translated into English by Miss Helen Zimmern, with a preface by the Rev. W. Arthur, London, 1876. (R. G.)

OCHRE. See Pigments.

OCKLEY, Simon (1678-1720), Orientalist, was born at Exeter in 1678. He was educated at Queens' College, Cambridge, and graduated B.A. in 1697, M.A. in 1701, and B.D. in 1710; he became fellow of Jesus College and vicar of Swavesey, and in 1711 was chosen Arabic professor of the university. He had a large family, and his latter days were embittered by pecuniary embarrassments, which form the subject of a chapter in D'Israeli's *Calamities of Authors*. The preface to the second volume of his *History of the Saracens* is dated from Cambridge castle, where he lay a prisoner for debt. He died in the year 1720. His chief work is *The History of the Saracens*, in 2 vols. 8vo, 1708-18, which long enjoyed a great reputation; unfortunately Ockley took as his main authority a MS. in the Bodleian of Pseudo-Wákidí's *Futúh al-Shám*, which is rather historical romance than history.

O'CLERY, Michael (born c. 1575). See Celtic Literature, vol. v. p. 307.

O'CONNELL, Daniel (1775-1847), born on 6th August, 1775, near Cahirciveen, a small town in Kerry, Ireland, was sprung from a race the heads of which had been Celtic chiefs, had lost their lands in the wars of Ireland, and had felt the full weight of the harsh penal code which long held the Catholic Irish down. His ancestors in the 18th century had sent recruits to the famous brigade of Irish exiles in the service of France, and those who remained at home either lived as tenants on the possessions of which they had once been lords, or gradually made money by smuggling, a very general calling in that wild region. Thus he inherited from his earliest years, with certain traditions of birth and high station, a strong dislike of British rule in Ireland and of the dominant owners of the soil, a firm attachment to his proscribed faith, and habitual skill in evading the law; and these influences may be traced in his subsequent career. O'Connell learned the rudiments at a school in Cork, one of the first which the state in those evil days allowed to be opened for Catholic teaching; and a few years afterwards he became a student, as was customary with Irish youths of his class, in the colleges of St Omer and Douai. His great abilities, it is said, were there perceived by the principals, and their peculiar training undoubtedly left a permanent mark on his mind and nature, for the casuistry and the diction of the Romish priesthood distinctly appear in his speeches and writings, and he had much of the ecclesiastic in his manners and bearing. These years, too, in France had, in another way, a decided effect in forming his judgment on political questions of high moment. He was an eye-witness on more than one occasion of the folly and excesses of the French Revolution; and these scenes not only increased his love for his church, but strongly impressed him with that dread of anarchy, of popular movements ending in bloodshed, and of communistic and socialistic views which characterized him in after life. To these experiences, too, we may partly ascribe the reverence for law, for the rights of property, and for the monarchical form of government which he appears to have sincerely felt; and, demagogue as he became in a certain sense, they gave his mind a deep Conservative tinge. In 1798 he was called to the bar of Ireland, and though, as professing a still degraded creed, he was shut out from the chance of promotion, though he could not even obtain a silk gown, and though, what was of more importance, he was subjected in a variety of ways to caste hostility, he rose before long to the very highest eminence among contemporary lawyers and advocates. This position was in the main due to a dexterity in conducting causes, and especially in examining witnesses, in which he had no rival at the Irish bar, and here his profound sagacity, observant cunning, and intuitive knowledge of the native character enabled him to accomplish wonders, even at the present day not wholly forgotten. He was, however, a thorough lawyer besides, inferior in scientific learning to two or three of his most conspicuous rivals, but well read in every department of law, and especially a master in all that relates to criminal and constitutional jurisprudence. As an advocate, too, he stood in the very highest rank; in mere oratory he was surpassed by Plunket, and in rhetorical gifts by Bushe, the only speakers to be named with him in his best days at the Irish bar; but his style, if not of the most perfect kind, and often

disfigured by decided faults, was marked by a peculiar subtlety and manly power, and produced great and striking effects. On the whole, in the art of winning over juries he had scarcely an equal in the law courts.

To understand, however, O'Connell's greatness we must look to the field of Irish politics. From early manhood he had turned his mind to the condition of Ireland and the mass of her people. The worst severities of the penal code had been, in a certain measure, relaxed, but the Catholics were still in a state of vassalage, and they were still pariahs compared with the Protestants. The rebellion of 1798 and the union had dashed the hopes of the Catholic leaders, and their prospects of success seemed very remote when, in the first years of the present century, the still unknown lawyer took up their cause. Up to this juncture the question had been in the hands of Grattan and other Protestants, and of a small knot of Catholic nobles and prelates; but their efforts had not accomplished much, and they aimed only at a kind of compromise, which, while conceding their principal claims, would have placed their church in subjection to the state. O'Connell inaugurated a different policy, and had soon given the Catholic movement an energy it had not before possessed. Himself a Catholic of birth and genius, unfairly kept back in the race of life, he devoted his heart and soul to the cause, and his character and antecedents made him the champion who ultimately assured its triumph. Having no sympathy with the rule of "the Saxon," he saw clearly how weak was the hold of the Government and the Protestant caste on the vast mass of the Catholic nation; having a firm faith in the influence of his church, he perceived that it might be made an instrument of immense political power in Ireland; and, having attained a mastery over the lawyer's craft, he knew how a great popular movement might be so conducted as to elude the law and yet be in the highest degree formidable. With these convictions, he formed the bold design of combining the Irish Catholic millions, under the superintendence of the native priesthood, into a vast league against the existing order of things, and of wresting the concession of the Catholic claims from every opposing party in the state by an agitation, continually kept up, and embracing almost the whole of the people, but maintained within constitutional limits, though menacing and shaking the frame of society. He gradually succeeded in carrying out his purpose: Catholic associations, at first small, but slowly assuming larger proportions, were formed in different parts of the country; attempts of the Government and of the local authorities to put them down were skilfully baffled by legal devices of many kinds; and at last, after a conflict of years, all Catholic Ireland was arrayed to a man in an organization of enormous power, that demanded its rights with no uncertain voice. O'Connell, having long before attained an undisputed and easy ascendency, stood at the head of this great national movement; but it will be observed that, having been controlled from first to last by himself and the priesthood, it had little in common with the mob rule and violence which he had never ceased to regard with aversion. His election for Clare in 1828 proved the forerunner of the inevitable change, and the Catholic claims were granted the next year, to the intense regret of the Protestant Irish, by a Government avowedly hostile to the last, but unable to withstand the overwhelming pressure of a people united to insist on justice. The result, unquestionably, was almost wholly due to the energy and genius of a single man, though the Catholic question would have been settled, in all probability, in the course of time; and it must be added that O'Connell's triumph, which showed what agitation could effect in Ireland, was far from doing his country unmixed good.

O'Connell joined the Whigs on entering parliament, and gave effective aid to the cause of reform. The agitation, however, on the Catholic question had quickened the sense of the wrongs of Ireland, and the Irish Catholics were engaged ere long in a crusade against tithes and the established church, the most offensive symbols of their inferiority in the state. It may be questioned whether O'Connell was not rather led than a leader in this; the movement, at least, passed beyond his control, and the country for many months was terrorized by scenes of appalling crime and bloodshed. Lord Grey, very properly, proposed measures of repression to put this anarchy down, and O'Connell opposed them with extreme vehemence, a seeming departure from his avowed principles, but natural in the case of a popular tribune. This caused a breach between him and the Whigs; but he gradually returned to his allegiance to them when they practically abolished Irish tithes, cut down the revenues of the established church, and endeavoured to secularize the surplus. By this time O'Connell had attained a position of great eminence in the House of Commons: as a debater he stood in the very first rank, though he had entered St Stephen's after fifty; and his oratory, massive and strong in argument, although too often scurrilous and coarse, and marred by a bearing in which cringing flattery and rude bullying were strangely blended, made a powerful, if not a pleasing, impression. O'Connell steadily supported Lord Melbourne's Government, gave it valuable aid in its general measures, and repeatedly expressed his cordial approval of its policy in advancing Irish Catholics to places of trust and power in the state, though personally he refused a high judicial office. These were not the least useful years of his life, and they clearly brought out the real character and tendencies of his views on politics. Though a strict adherent of the creed of Rome, he was a Liberal, nay a Radical, as regards measures for the vindication of human liberty, and he sincerely advocated the rights of conscience, the emancipation of the slave, and freedom of trade. But his rooted aversion to the democratic theories imported from France, which were gradually winning their way into England, only grew stronger with advancing age; he denounced Chartism in unmeasured terms; the sovereign had no more loyal subject; and if, as became him, he often condemned the tyranny of bad Continental Governments, he reverenced the constitution and laws of England interpreted in a generous spirit. His conservatism, however, was most apparent in his antipathy to socialistic doctrines and his tenacious regard for the claims of property. He actually opposed the Irish Poor Law, as encouraging a communistic spirit; he declared a movement against rent a crime; and, though he had a strong sympathy with the Irish peasant, and advocated a reform of his precarious tenure, it is difficult to imagine that he could have approved the cardinal principle of the Irish Land Act, the judicial adjustment of rent by the state.

O'Connell changed his policy as regards Ireland when Peel became minister in 1841. He declared that a Tory régime in his country was incompatible with good government, and he began an agitation for the repeal of the union. One of his motives in taking this course no doubt was a strong personal dislike of Peel, with whom he had often been in collision, and who had singled him out in 1829 for what must be called a marked affront. O'Connell, nevertheless, was sincere and even consistent in his conduct: he had denounced the union in early manhood as an obstacle to the Catholic cause; he had spoken against the measure in parliament; he believed that the claims of Ireland were set aside or slighted in what he deemed an alien assembly; and, though he had ceased for some years to demand repeal, and regarded it as rather a means

than an end, he was throughout life an avowed repealer. It should be observed, however, that in his judgment the repeal of the union would not weaken the real bond between Great Britain and Ireland; and he had nothing in common with the rebellious faction who, at a later period, openly declared for the separation of the two countries by force. The organization which had effected such marvellous results in 1828-29 was recreated for the new project. Enormous meetings, convened by the priesthood, and directed or controlled by O'Connell, assembled in 1842-43, and probably nine-tenths of the Irish Catholics were unanimous in the cry for repeal. O'Connell seems to have thought success certain; but he had not perceived the essential difference between his earlier agitation and this. The enlightened opinion of the three kingdoms for the most part approved the Catholic claims, and as certainly it condemned repeal. After some hesitation Peel resolved to put down the repeal movement. A vast intended meeting was proclaimed unlawful, and O'Connell was arrested and held to bail, with ten or twelve of his principal followers. He was convicted after the trials that followed, but they were not good specimens of equal justice, and the sentence was reversed by the House of Lords, with the approbation of competent judges. The spell, however, of O'Connell's power had vanished; his health had suffered much from a short confinement; he was verging upon his seventieth year; and he was alarmed and pained by the growth of a party in the repeal ranks who scoffed at his views, and advocated the revolutionary doctrines which he had always feared and abhorred. Before long famine had fallen on the land, and under this visitation the repeal movement, already paralysed, wholly collapsed. O'Connell died soon afterwards, on 15th May 1847, at Genoa, whilst on his way to Rome, profoundly afflicted by his country's misery, and by the failure of his late high hopes, yet soothed in dying by sincere sympathy, felt throughout Ireland and largely in Europe, and expressed even by political foes. He was a remarkable man in every sense of the word; Catholic Ireland calls him her "Liberator" still; and history will say of him that, with some failings, he had many and great gifts, that he was an orator of a high order, and that, agitator as he was, he possessed the wisdom, the caution, and the tact of a real statesman. O'Connell married in 1802 his cousin Mary O'Connell, by whom he had three daughters and four sons. Of the latter, all have at one time or another had seats in parliament. (W. O. M.)

O'CONNOR, FEARGUS EDWARD (1796-1855), Chartist leader, was born in 1796, and entered parliament as member for the county of Cork in 1832. Though a zealous supporter of repeal, he endeavoured to supplant O'Connell as the leader of the party, an attempt which aroused against him the popular antipathy of the Irish. When, therefore, in 1834 he was unseated on petition, he resolved to go to England, where he established the *Northern Star* newspaper, and became a vehement advocate of the Chartist movement. In 1847 he was returned for Nottingham, and in 1848 he presided at a Chartist demonstration in London, which caused great alarm. (See CHARTISM, vol. v. p. 434.) The eccentricity and extravagance which had characterized his opinions from the beginning of his career gradually became more marked until they developed into insanity. He began to conduct himself in a strange and disorderly manner in the House of Commons, and in 1853 he was found to be of unsound mind by a commission of lunacy. He died at London 30th August 1855, and was buried in Kensal Green cemetery.

OCTAVIA. (1.) Octavia, daughter of Caius Octavius, prætor, 61 B.C., and sister of the emperor Augustus, was married to C. Marcellus, one of the bitterest enemies of Julius Cæsar. In 41 her husband died, and she was married immediately to Antony, with the design of securing peace between her brother and her new husband. Her beauty and her high character are praised in the warmest terms by all authorities, and at first Antony devoted himself to her, and seemed to have forgotten his jealousy of her brother and his old love for Cleopatra. But his affection for his wife was not strong enough to counterbalance the feelings that weighed against it. In the year 36 he went off to the Parthian war and to meet Cleopatra, and, when in the following year Octavia brought out troops and money to him, he refused to see her and bade her go back to Rome. She sent the money to him and returned to his house, where she educated his son by a former wife along with her own children. In 32 Antony formally divorced her, but she always protected his children, even those of Cleopatra. She died 11 B.C., and was buried with the highest honours by the state. (2.) Octavia, daughter of the emperor Claudius, was married in her twelfth year to NERO (*q.v.*). A Latin tragedy on her fate is attributed, though wrongly, to Seneca.

OCTOBER, the eighth month of the old Roman year, which began in spring. By the Julian arrangement, while retaining its old name, it became the tenth month, and had thirty-one days assigned to it. The meditrinalia, when a libation of new wine was made in honour of Meditrina, were celebrated on the 11th, the faunalia on the 13th, and the equiria, when the "equus October" was sacrificed to Mars in the Campus Martius, on the 15th. The principal ecclesiastical feasts in October are those of St Luke on the 18th and of St Simon and St Jude on the 28th. By the Slavs this is called "yellow month," from the fading of the leaf; to the Anglo-Saxons it was known as Winterfylleth, because at this full moon (fylleth) winter was supposed to begin. It corresponds partly to the Vendémiaire and partly to the Brumaire of the first French republic.

OCTOPUS. See CUTTLEFISH, vol. vi. p. 735; and MOLLUSCA, vol. xvi. p. 669 *sq.*

OCYDROME, a word formed from *Ocydromus*, meaning "swift-runner," and suggested by Wagler in 1830 as a generic term for the New-Zealand bird called in the then unpublished manuscripts of the elder Forster *Rallus troglodytes*, and so designated in 1788 by Gmelin, who knew of it through Latham's English description. Wagler's suggestion has since been generally adopted, and the genus *Ocydromus* is accepted by most ornithologists as a valid group of *Rallidæ*; but the number of species it contains is admittedly doubtful, owing to the variability in size and plumage which they exhibit, and their correct nomenclature must for the present be considered uncertain. Mr Buller in his *Birds of New Zealand* identifies the "Wood-hen," observed in great abundance on the shores of Dusky Bay in 1773 by Cook and his companions on his second voyage, with the *Gallirallus fuscus* described and figured by Du Bus in 1847, and accordingly calls it *O. fuscus*; but it cannot be questioned that the species from this locality—which appears to have a somewhat limited range in the Middle Island,[1] and never to be met with far from the sea-coast, where it lives wholly on crustaceans and other marine animals—is identical with that of the older authors just mentioned. In 1786 Sparrman, who had also been of Cook's company, figured and described as *Rallus australis* a bird which, though said by him to be that of the southern coast of New Zealand, differs so much from the *R. troglodytes* as to compel a belief in its specific distinctness; and

[1] It also occurs in Stewart Island, and singularly enough on the more distant group known as the Snares. The *Galliralluus brachypterus* of Lafresnaye, of which the typical (and unique ?) specimen from an unknown locality is in the Caen Museum, has also been referred to this species, but the propriety of the act may be doubted.

indeed his species has generally been identified with the common "*Weeka*" of the Maories of the Middle Island, which can scarcely be the case if his statement is absolutely true, since the latter does not appear to reach so far to the southward, or to affect the sea-shore. It may therefore be fairly inferred that his subject was obtained from some other locality. The North Island of New Zealand has what is allowed to be a third species, to which the name of *Ocydromus earli* is attached, and this was formerly very plentiful; but its numbers are rapidly decreasing, and there is every chance of its soon being as extinct as is the species which tenanted Norfolk Island on its discovery by Cook in 1774, and was doubtless distinct from all the rest, but no specimen of it is known to exist in any museum.[1] Another species, *O. sylvestris*, smaller and lighter in colour than any of the rest, was found in 1869 to linger yet in Lord Howe's Island (*Proc. Zool. Society*, 1869, p. 472, pl. xxxv.). Somewhat differing from *Ocydromus*, but apparently very nearly allied to it, is a little bird peculiar, it is believed, to the Chatham Islands (*Ibis*, 1872, p. 247), and now regarded by Captain Hutton as the type of a genus *Cabalus* under the name of *C. modestus*, while other naturalists consider it to be the young of the rare *Rallus dieffenbachi*. So far the distribution of the Ocydromine form is wholly in accordance with that of most others characteristic of the New-Zealand sub-region; but a curious exception is asserted to have been found in the *Gallirallus lafresnayanus* of New Caledonia, which, though presenting some structural differences, has been referred to the genus *Ocydromus*.

The chief interest attaching to the Ocydromes is their inability to use in flight the wings with which they are furnished, and hence an extreme probability of the form becoming wholly extinct in a short time. Of this inability there are other instances among the *Rallidæ* (see MOORHEN, vol. xvi. p. 808); but here we have coupled with it the curious fact that in the skeleton the angle which the scapula makes with the coracoid is greater than a right angle, a peculiarity shared only, so far as is known, among the *Carinatæ* by the Dodo. The Ocydromes are birds of dull plumage, and mostly of retiring habits, though the common species is said to show great boldness towards man, and, from the accounts of Cook and the younger Forster, the birds seen by them displayed little fear. It is also declared that they will interbreed with common poultry, and more than one writer vouches for the truth of this extraordinary statement. It is to be hoped that the naturalists of New Zealand will not allow the form to become extinct if any effectual means can be taken to perpetuate it; but, should that fate be inevitable, it at least behoves the present generation to see that every possible piece of information concerning the birds be recorded, and every possible preparation illustrating their structure be made, while yet there is time; for, though much has been written on the subject, it is obvious from one of the latest papers (*Trans. New Zealand Institute*, x. p. 213) that there is still more to be learned, some of which may throw further light on the affinities of the birds of the extinct genus *Aptornis*. (A. N.)

ODDFELLOWS, a name adopted by the members of certain social institutions having mystic signs of recognition, initiatory rites and ceremonies, and various grades of dignity and honour. The objects the associations have in view are purely social and benevolent; the sphere of their operations is confined wholly to their own members, and secrecy is enjoined in regard to all benevolent acts. As in the case of most other institutions of a similar kind, a claim of venerable antiquity has been set up for the order of Oddfellows,—the most common account of its origin ascribing it to the Jewish legion under Titus, who, it is asserted, received from that emperor its first charter written on a golden tablet. Statements even more improbable and fantastic have been made regarding its foundation, but Oddfellows themselves now generally admit that the institution cannot be traced to an earlier period than the first half of the 18th century, and explain the name as adopted at a time when the severance into sects and classes was so wide that persons aiming at social union and mutual help were a marked exception to the general rule. Mention is made by Defoe of the society of Oddfellows, but the oldest lodge of which the name has been handed down is the Loyal Aristarcus, No. 9, which met in 1745 "at the Oakley Arms, Borough of Southwark; Globe Tavern, Hatton Garden; or the Boar's Head in Smithfield, as the noble master may direct." The earliest lodges were supported by each member and visitor paying a penny to the secretary on entering the lodge, and special sums were voted to any brother in need. If out of work he was supplied with a card and funds to reach the next lodge, and he went from lodge to lodge until he found employment. Now there is a regular system of periodical dues and collections, with occasional fees proportioned to the dignities or degrees conferred in the lodges. At first each lodge was practically independent of the others, and had its own special rules and government, but a close bond of unity gradually grew up between the large majority of the lodges until they adopted a definite common ritual and became confederated under the name of the Patriotic Order. Towards the end of the century many of the lodges were broken up by State prosecutions on the suspicion that their purposes were "seditious," but the society, changing its name and location, continued to exist in a sort of moribund condition, as the Union Order of Oddfellows, until in 1809 several of the members endeavoured to resuscitate its dormant energies. Finding, however, that it was impossible to excite an interest in anything higher than convivial meetings, they in 1813, at a convention in Manchester, formally seceded from the Union Order and formed the Independent Order of Oddfellows, Manchester Unity, which increased with enormous rapidity, and now overshadows all the minor societies in England. According to the *Oddfellows' Magazine* for October 1883, the membership of the order in 1834 was 32,832, which in 1837 had increased to 80,570 and in 1845 to 239,374, while in January 1883 the numbers had risen to 565,368, the lodges amounting to 4251. In 1881 the receipts were £761,695, the payments £531,335, and the capital £5,291,891. In 1850 the society was legalized and recognized by the state in a corporate capacity. The *Oddfellows' Magazine*, issued by the society, and up to October 1883 published quarterly, now appears monthly. In England there are a large number of minor orders of Oddfellows, which either existed before the Manchester Unity, have seceded from it, or have had an independent origin. Among them are the Ancient Independent Order or Kent Unity, Woolwich, 1805, revived 1861; the Nottingham Ancient Imperial Order, 1812; the London Unity, 1820; the Boston Unity, 1832; the Kingston Unity, 1840; the Norfolk and Norwich Unity, 1849; and the Derby Midland United Order, 1856.

Oddfellowship was introduced into the United States

[1] As before stated (NESTOR, p. 354 *ante*), the younger Forster remarked that the birds of Norfolk Island, though believed by the other naturalists of Cook's ship to be generally the same as those of New Zealand, were distinguished by their brighter colouring. There can now be little doubt that all the land-birds were specifically distinct. It seems to be just possible that Sparrman's *R. australis*, which cannot be very confidently referred to any known species of *Ocydromus*, may have been from Norfolk Island; but there is little probability of the point ever being determined, though it seems to be worth the attention of ornithologists.

from the Manchester Unity in 1819, and the grand lodge of Maryland and the United States was constituted 22d February 1821. At first the progress of the order was slow, but, as may be supposed from the social characteristics and proclivities of the Americans, as soon as it had gained a firm hold its principles spread with great rapidity, and it now rivals in membership and influence the Manchester Unity, from which it severed its connexion in 1842. In 1843 it issued a dispensation for opening the Prince of Wales Lodge No. 1 at Montreal, Canada. The American society, including Canada and the United States, has its headquarters at Baltimore. In 1882 the membership was said to be 500,000, the income 6,000,000 dollars, and the annual sum disbursed for the relief of members of the order 2,000,000 dollars. Organizations, connected either with the United States or England, have been founded in Germany, Switzerland, Gibraltar and Malta, Australia, New Zealand, the Fiji Islands, the Hawaiian Islands, South Africa, South America, the West Indies, and Barbados.

The rules of the different societies, various song-books, and a number of minor books on Oddfellowship have been published, but the most complete and trustworthy account of the institution is that in *The Complete Manual of Oddfellowship, its History, Principles, Ceremonies, and Symbolism*, privately printed, 1879.

ODENATHUS, or ODÆNATHUS (Ὀδαίναθος, ארינת), prince of Palmyra. See PALMYRA and PERSIA.

ODENSE, a city of Denmark, the chief town of the province of the same name, forming the northern part of the island of Fünen (Fyen), lies about 4 miles from Odense Fjord on the Odense Aa, the main portion on the north side of the stream and the modern Albani quarter on the south side. It is a station on the railway route between Copenhagen and western Denmark, and a ship canal 10 feet deep constructed in 1796-1804 affords direct communication with the sea. St Canute's Church, formerly connected with the great Benedictine monastery of the same name, is one of the largest and finest edifices of its kind in Denmark. It is constructed of brick in a pure Gothic style. Originally dating from 1081-93, it was rebuilt in the 13th century, and has been restored since 1864. Under the altar lies Canute, the patron saint of Denmark, who intended to dispute with William of Normandy the possession of England, but was slain in an insurrection at Odense in 1086; Kings John and Christian II. are also buried within the walls. Our Lady's Church, built in the 13th century and restored in 1851-52 and again in 1864, contains a fine carved altar-piece by Claus Berg of Lübeck. Odense castle was erected by Frederick IV., who died there in 1730. The provincial infirmary (1862), the new post-office, the Franciscan hospital, presented to Fünen in 1539 by King Christian III., Frederick VII.'s foundation (1862), the episcopal library (25,000 volumes), and Karen Brahe's library may also be mentioned. As an industrial town Odense has made great progress since the middle of the century; besides a large number of breweries and distilleries, it contains glove-factories, match works, mineral-water works, tobacco-factories, chemical works, &c. The population was 5782 in 1801, 11,122 in 1850, 16,970 in 1870, and 20,804 in 1880.

Odense, or Odinsey, originally Odinsoe, *i.e.*, Odin's sanctuary, is one of the oldest, as it has long been one of the most important, cities of Scandinavia. St Canute's shrine was a great resort of pilgrims throughout the Middle Ages. In the 16th century the town was the meeting-place of several parliaments, and down to 1805 it was the seat of the provincial assembly of Funen. It was the first place in Denmark to introduce gas-light (in the close of 1853). Hans Andersen was born in Odense, and Kingo, the Danish hymn-writer, was bishop of the diocese. Paludan-Muller, a native of the neighbouring town of Kjerteminde, was educated in the Odense cathedral school.

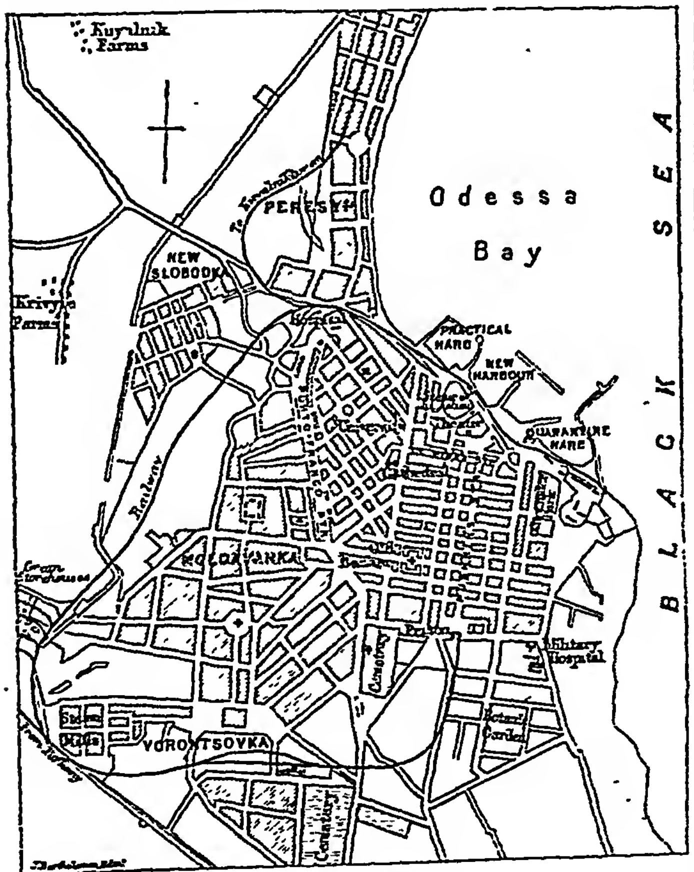
ODER (Latin, *Viadrus*; Slavonic, *Vjodr*), one of the principal rivers of Germany, rises on the Odergebirge in the Moravian tableland, in 49° 43′ N. lat. and 17° 35′ E. long., at a height of 1950 feet above the sea, and 14 miles to the east of Olmütz. It is 550 miles long from its source to its mouth in the Baltic Sea, and drains an area of about 50,000 square miles. The first 45 miles of its course lie within Moravia; for the next 15 it forms the frontier between Prussian and Austrian Silesia; while the remaining 490 miles belong to Prussia, where it traverses the provinces of Silesia, Brandenburg, and Pomerania. It flows at first towards the south-east, but on quitting Austria turns towards the north-west, maintaining this direction as far as Frankfort, beyond which its general course is nearly due north. As far as the frontier the Oder flows through a well-defined valley, but, after passing through the gap between the Moravian mountains and the Carpathians and entering the Silesian plain, its valley is wide and shallow and its banks generally low. In its lower course it is divided into numerous branches, forming a large quantity of islands. The main channel follows the left side of the valley and finally expands into the Pommersche or Stettiner Haff, which is connected with the sea by three arms, the Peene, the Swine, and the Dievenow, forming the islands of Usedom and Wollin. The Swine, in the middle, is the main channel for navigation. The chief tributaries of the Oder on the left bank are the Oppa, Glatz Neisse, Katzbach, Bober, and Lausitz Neisse; on the right bank the Malapane, Bartsch, Faule Obra, and Warthe. Of these the only one of importance for navigation is the Warthe, which through the Netze is brought into communication with the Vistula. The Oder is also connected by canals with the Havel and the Spree. The most important towns on its banks are Ratibor, Oppeln, Brieg, Breslau, Glogau, Frankfort, Cüstrin, and Stettin, with the seaport of Swinemünde at its mouth. Glogau and Cüstrin are strongly fortified, and Swinemünde is also defended by a few forts.

The navigation of the Oder is rendered somewhat difficult by the rapid fall of its upper course, amounting above Brieg to 2 feet per mile, and by the enormous quantities of débris brought into it by its numerous mountain tributaries. The German authorities, however, have been unwearied in their efforts to improve the channel, and have now succeeded in securing a minimum depth of 3 feet at low water throughout almost the whole of the Prussian part of the river. Their most important undertaking was the diversion of the river into a new and straight channel in the Oderbruch below Frankfort, by which an extensive detour was cut off and a large tract of swampy country brought under cultivation. The Oder at present begins to be navigable for barges at Ratibor, where it is about 100 feet wide, but the navigable channel will probably soon extend upwards to Oderberg. Sea-going vessels cannot go beyond Stettin. A second Oder-Spree canal, leaving the Oder opposite the mouth of the Warthe and joining the Spree near Berlin, has been determined on; and a canal connecting the Oder and the Danube has also been planned. The traffic on the Oder, which is steadily increasing, is mainly concerned with agricultural produce and timber. Some idea of its extent may be gathered from the fact that 280 river-steamers and 2800 other vessels passed through the Oderbruch (up and down) in 1881 with cargoes amounting in all to 166,500 tons. The river is here about 750 feet wide and 8 feet deep. The fishing is important, particularly in the neighbourhood of Stettin.

Those interested in river navigation or engineering may be referred to the following works: Becker, *Zur Kenntniss der Oder und ihres Flachengebiets* (1868); "Die Deutschen Wasserstrassen" in the *Statistik des Deutschen Reiches* for 1874; Haase, *Regulation der deutschen Hauptstrome* (Breslau, 1880).

ODESSA, one of the most important seaports of Russia, ranks in the empire by its population (225,000) and foreign trade after St Petersburg, Moscow, and Warsaw. It is situated in 46° 28′ N. lat. and 30° 44′ E. long., on the southern shore of a semicircular bay, at the north-western angle of the Black Sea, and is 933 miles distant from Moscow and 403 miles from Kieff. Odessa is the proper seaport for the basins of two great rivers of Russia, the Dnieper, with its tributary the Bug, and the Dniester; the entrances to the mouths of both these offering many difficulties for navigation, trade has from the remotest antiquity selected this spot, which is situated half-way between the estuaries, while the flat ground of the neighbouring steppe allows

easy communication with the lower parts of both rivers. The *limans* or lagoons of Haji-bey and Kuyalnik, which penetrate far inland from the neighbourhood of Odessa, are separated from the sea by flat sandy isthmuses. The bay of Odessa, which has an area of 14 square miles and a depth of 30 feet, with a soft bottom, is a dangerous anchorage on account of its exposure to easterly winds. The ships lie, therefore, in two harbours, both protected by moles,—the "quarantine harbour," from 4 to 21 feet deep, and the so-called "practical harbour," for coasting vessels, with a maximum depth of 11 feet. A new one, 1100 yards long and 660 yards wide, was constructed a few years ago. The harbours freeze for a few days in winter, as also does the bay itself occasionally, navigation being interrupted every year for an average of sixteen days. Odessa experiences the influence of the continental climate of the neighbouring steppes; its winters are cold (the average temperature for January being 23°·2, and the isotherm for the entire season that of Königsberg), its summers are hot (72°·8 in July), and the yearly average



Plan of Odessa.

temperature is 48°·5. The rainfall is scanty (ninety-two rainy days, with 14 inches of rain per annum); and one of the plagues of the city is the chalky dust, which is raised in clouds by the strong winds to which it is exposed. The city is built on a terrace from 100 to 150 feet in height, which descends by steep crags to the sea, and on the other side is continuous with the level of the steppe, which is covered with a layer of "black earth"; the subsoil consists of clay, gravel, and a soft Tertiary sandstone, which is used for building, but readily disintegrates under atmospheric agencies. Catacombs whence this sandstone has been taken extend underneath the town and the suburbs, not without some danger to the buildings. The water-supply is inadequate. Drinking-water was formerly shipped from the Crimea, and the poorer classes had to supply themselves from cisterns and bad wells. An aqueduct, 27 miles long, now brings water from Mayaki on the Dniester.

The general aspect of Odessa is that of a wealthy West-European city. Its chief embankment, bordered with tall and handsome houses, forms a fine promenade; a superb flight of steps descends to the sea from its central square, which is adorned with a statue of Richelieu. The central parts of the city have broad streets and squares, bordered with fine buildings and mansions in the Italian style, and with good shops. But even on the best streets poor houses surrounded with open yards occur side by side with richly-decorated palaces; and in close association with elegant carriages and rich dresses one sees the open car of the peasant and the dirty dress of the Jew or the Bulgarian. The cathedral, finished in 1849, can accommodate 5000 persons; it contains the tomb of Count Worontzoff, a former governor-general, who contributed much towards the development and embellishment of the city. The "Palais Royal," with its parterre and fountains, and the spacious public park are fine pleasure-grounds, whilst in the ravines that descend to the sea the dirty houses of the poorer classes are massed. The shore is occupied by immense granaries, some of which look like palaces, and large storehouses take up a broad space in the west of the city. Odessa, which has a circumference of 6 miles, consists of the city proper, containing the old fort (now a quarantine establishment) and surrounded by a boulevard, where was formerly a wall marking the limits of the free port, of the suburbs Novaya and Peresyp, extending northward along the lower shore of the bay, and of Moldavanka to the south-west. A number of villas and cottages surround the city; the German colonies Liebenthal and Lustdorf are bathing-places.

Odessa is the real capital, intellectual and commercial, of the so-called Novorossia, which includes the governments of Bessarabia and Kherson. In the official subdivision of Russia it is only the chief town of the district of the same name in the government of Kherson. It constitutes at the same time an independent "municipal district" or captaincy (*gradonachalstvo*), which covers 182 square miles and includes a dozen villages, some of which have from 2000 to 3000 inhabitants. Odessa, like St Petersburg and Moscow, received in 1863 a new municipal constitution, with an elective mayor, municipal assembly, and executive council. It is also the chief town of the Novorossian educational district, and has a university, which replaced Richelieu Lyceum in 1865, and now has about 400 students. The young scientific society at the university is very active in investigating the natural history of southern Russia and of the Black Sea, and has already published some valuable *Transactions*. There are also an historical society with a museum containing rich collections from the Hellenic, Genoese, Venetian, and Mongolo-Tatar periods of the history of the Black Sea coast, a society of agriculture, a public library, and many educational institutions.

The population of Odessa is rapidly increasing. In 1814, twenty years after its foundation, it had 25,000 inhabitants; this figure steadily grew in succeeding years, Worontzoff allowing all sorts of people, runaway serfs included, to settle in the steppes of Bessarabia and Kherson, while at the same time the privileges of a free port, granted in 1817 and abolished only in 1857, attracted great numbers of merchants of all nationalities. In 1850 Odessa had 100,000 inhabitants, 185,000 in 1873, and at present (1884) the number exceeds 225,000. Of these the great majority are Great Russians and Little Russians; but there are also large numbers of Jews (67,000, exclusive of Karaites, against 50,000 in 1873), as well as of Italians, Greeks, Germans, and French (to which nationalities the chief merchants belong), as also of Roumanians, Servians, Bulgarians, Tatars, Armenians, Lazes, Georgians, &c. These nationalities do not live in perfect harmony, and the continual commercial antagonism between the Greeks and the Jews often leads to scenes of disorder. A numerous floating population of labourers, attracted at certain periods by pressing work in the port, and afterwards left unemployed owing to the enormous fluctuations in the corn trade, is one of the features of Odessa. It is estimated that there are no less than 35,000 people living from hand to mouth in the utmost misery, partly in the extensive labyrinth of the catacombs beneath the city.

The leading occupations of the inhabitants are connected with exporting, shipping, and manufactures. These latter have extended rapidly within the last twenty years, but their aggregate production (in the *gradonachalstvo* of Odessa) does not exceed 20,000,000 roubles (about £2,000,000). To this total the principal items are contributed by the steam flour-mills (about £650,000 in 1879), the manufacture of tobacco (£200,000) and of machinery (£200,000), after which come tanneries, soap-works, chemical-works, biscuit-

factories, rope-works, and carriage-works. The foreign trade, chiefly in corn, has immensely increased of late, since Odessa was brought into railway communication with central Russia. Grain was exported in 1880 to the amount of 1,040,400 quarters (2,445,120 quarters in 1878). This figure is subject, however, to great fluctuations. The other articles of export are flour, wool, tallow, hides, cattle (about 140,000 head), soap, ropes, and spirits, the value of the aggregate amount of exports reaching 42,000,000 roubles in 1880, against 65,000,000 roubles in 1879, and 85,815,000 in 1878. The chief articles of import are tea (£1,600,000 in 1881), coffee, rice, cotton, tobacco, coal, oil, leather, paper, fruits, wine, and all kinds of manufactured ware, for an aggregate sum of 47,775,000 roubles in 1880. Odessa also carries on a brisk trade with other seaports of Russia, and, besides the 1508 ships (282 Russian and 650 English) engaged in foreign trade which entered the port of Odessa in 1879, it was visited by 2700 coasting vessels. Odessa is in regular steam communication with all the chief ports of the Black Sea and the Mediterranean, as also with London. The Russian Navigation Company sends its steamers by the Suez Canal to Chinese, Indian, and Russian Pacific ports, and has a numerous fleet on the Dnieper, Dniester, and Bug. The commercial fleet of Odessa in 1880 numbered 101 steamers (44,000 tons) and 178 sailing ships (19,800 tons). The total revenue of the town in 1882 was 1,938,000 roubles, and the expenditure 1,883,000 roubles,—the chief items being, for charitable institutions 434,000 roubles, for the army 213,000, for administration and police 309,000, and for public instruction 138,000.

History.—The bay of Odessa was colonized by Greeks at a very early period, and their ports—Istrianorum Portus and Isiacorum Portus on the shores of the bay, and Odessus and the modern Skopeli at the mouth of the Tiligul *liman*—carried on a lively trade with the neighbouring steppes. These towns disappeared in the 3d and 4th centuries, leaving nothing but heaps of ruins; and for ten centuries thenceforward no settlements in these tracts are mentioned. All that is known is that in the 6th century the space between the mouths of the Dnieper and the Dniester was occupied by the Antes, and in the 9th century by the Tivertsy, both of Slavonian origin. In the 14th century this region belonged to the Lithuanians, and in 1396 Olgerd defeated in battle three Tatar chiefs, one of whom, Bek-Haji, had recently founded, at the place now occupied by Odessa, a fort which received his name. The Lithuanians, and subsequently the Poles, kept the country under their dominion until the 16th century, when it was seized by the Tatars, who still permitted, however, the Lithuanians to gather salt in the neighbouring lakes. Later on the Turks left a garrison at Haji-bey, and founded in 1764 the fortress Yanidunia. In 1769 the Zaporog Cossacks made a raid on Haji-bey and burned its suburbs, but could not take the fort; and, after the destruction of the Zaporojskaya Sech, the runaway Zaporogians settled close by Haji-bey in what is now the "quarantine ravine." In 1787 the Cossack leader Chepega again attacked Haji-bey and burned all its storehouses, and two years later the Russians, under the French captain De Ribas, took the fortress by assault. In 1791 Haji-bey and the Otchakoff region were conceded to Russia. De Ribas and the French engineer Voland were entrusted in 1794 with the erection of a town and the construction of a port at Haji-bey; the former was allowed to distribute about 100,000 acres of land freely to new settlers, and two years later Haji-bey, renamed Odessa, had 3153 permanent inhabitants, besides the military, and was visited by 86 foreign vessels. In 1803 Odessa became the chief town of a separate municipal district or captaincy, the first captain being the duke of Richelieu, who did very much for the development of the young city and its improvement as a seaport. In 1824 Odessa became the seat of the governors-general of Novorossia and Bessarabia. Since that time it has steadily increased its foreign trade and extended its commercial relations. In 1866 it was brought into railway connexion with Kieff and Kharkoff *via* Balta, and with Jassy in Roumania. (P. A. K.)

ODOACER, or **ODOVACAR** (*c.* 434-493), the first barbarian ruler of Italy on the downfall of the Western empire, was born in the district bordering on the middle Danube about the year 434. In this district the once rich and fertile provinces of Noricum and Pannonia were being torn piecemeal from the Roman empire by a crowd of German tribes, among whom we discern four, who seem to have hovered over the Danube from Passau to Pesth, namely, the Rugii, Scyrri, Turcilingi, and Heruli. With all of these Odoacer was connected by his subsequent career, and all seem, more or less, to have claimed him as belonging to them by birth; the evidence slightly preponderates in favour of his descent from the Scyrri.

His father was Ædico or Idico, a name which suggests Edeco the Hun, who was suborned by the Byzantine court to plot the assassination of his master Attila. There are, however, some strong arguments against this identification. A certain Edica, chief of the Scyrri, of whom Jordanes speaks as defeated by the Ostrogoths, may more probably have been the father of Odoacer, though even in this theory there are some difficulties, chiefly connected with the low estate in which he appears before us in the next scene of his life, when as a tall young recruit for the Roman armies, dressed in a sordid vesture of skins, on his way to Italy, he enters the cell of Severinus, a noted hermit-saint of Noricum, to ask his blessing. The saint had an inward premonition of his future greatness, and in blessing him said, "Fare onward into Italy. Thou who art now clothed in vile raiment wilt soon give precious gifts unto many."

Odoacer was probably about thirty years of age when he thus left his country and entered the imperial service. By the year 472 he had risen to some eminence, since it is expressly recorded that he sided with the patrician Ricimer in his quarrel with the emperor Anthemius. In the year 475, by one of the endless revolutions which marked the close of the Western empire, the emperor Nepos was driven into exile, and the successful rebel Orestes was enabled to array in the purple his son, a handsome boy of fourteen or fifteen, who was named Romulus after his grandfather, and nicknamed Augustulus, from his inability to play the part of the great Augustus. Before this puppet emperor had been a year on the throne the barbarian mercenaries, who were chiefly drawn from the Danubian tribes before mentioned, rose in mutiny, demanding to be made proprietors of one-third of the soil of Italy. To this request Orestes returned a peremptory negative. Odoacer now offered his fellow-soldiers to obtain for them all that they desired if they would seat him on the throne. On the 23d August 476 he was proclaimed king; five days later Orestes was made prisoner at Placentia and beheaded; and on the 4th September his brother Paulus was defeated and slain in the pine-wood near Ravenna. Rome at once accepted the new ruler. Augustulus was compelled to descend from the throne, but his life was spared.

Odoacer was forty-two years of age when he thus became chief ruler of Italy, and he reigned thirteen years with undisputed sway. Our information as to this period is very slender, but we can perceive that the administration was conducted as much as possible on the lines of the old imperial government. The settlement of the barbarian soldiers on the lands of Italy probably affected the great landowners rather than the labouring class. To the herd of *coloni* and *servi*, by whom in their various degrees the land was actually cultivated, it probably made little difference, except as a matter of sentiment, whether the master whom they served called himself Roman or Rugian. We have one most interesting example, though in a small way, of such a transfer of land with its appurtenant slaves and cattle, in the donation made by Odoacer himself to his faithful follower Pierius.[1] Few things bring more vividly before the reader the continuity of legal and social life in the midst of the tremendous ethnical changes of the 5th century than the perusal of such a record.

The same fact, from a slightly different point of view, is illustrated by the curious history (recorded by Malchus) of the embassies to Constantinople. The dethroned emperor Nepos sent ambassadors (in 477 or 478) to Zeno emperor

[1] Published in Marini's *Papiri Diplomatici* (Rome, 1815, Nos. 82 and 83) and in Spangenberg's *Juris Romani Tabulæ* (Leipsic, 1822, pp. 164-173), and well worthy of careful study.

of the East, begging his aid in the reconquest of Italy. These ambassadors met a deputation from the Roman senate, sent nominally by the command of Augustulus, really no doubt by that of Odoacer, the purport of whose commission was that they did not need a separate emperor. One was sufficient to defend the borders of either realm. The senate had chosen Odoacer, whose knowledge of military affairs and whose statesmanship admirably fitted him for preserving order in that part of the world, and they therefore prayed Zeno to confer upon him the dignity of patrician, and entrust the "diocese" of Italy to his care. Zeno returned a harsh answer to the senate, requiring them to return to their allegiance to Nepos. In fact, however, he did nothing for the fallen emperor, but accepted the new order of things, and even addressed Odoacer as patrician. On the other hand, the latter sent the ornaments of empire, the diadem and purple robe, to Constantinople as an acknowledgment of the fact that he did not claim supreme power. Our information as to the actual title assumed by the new ruler is somewhat confused. He does not appear to have called himself king of Italy. His kingship seems to have marked only his relation to his Teutonic followers, among whom he was "king of the Turcilingi," "king of the Heruli," and so forth, according to the nationality with which he was dealing. By the Roman inhabitants of Italy he was addressed as "dominus noster," but his right to exercise power would in their eyes rest, in theory, on his recognition as patricius by the Byzantine Augustus. At the same time, he marked his own high pretensions by assuming the prefix Flavius, a reminiscence of the early emperors, to which the barbarian rulers of realms formed out of the Roman state seem to have been peculiarly partial. His internal administration was probably, upon the whole, wise and moderate, though we hear some complaints of financial oppression, and he may be looked upon as a not altogether unworthy predecessor of Theodoric.

In the history of the papacy Odoacer figures as the author of a decree promulgated at the election of Felix II. in 483, forbidding the pope to alienate any of the lands or ornaments of the Roman Church, and threatening any pope who should infringe this edict with anathema. This decree, a strange one to proceed from an Arian sovereign, was probably suggested by some of the Roman counsellors of the king, and seems to have been accepted at the time without protest. It was, however, loudly condemned in a synod held by Pope Symmachus (502) as an unwarrantable interference of the civil power with the concerns of the church.

The chief events in the foreign policy of Odoacer were his Dalmatian and Rugian wars. In the year 480 the ex-emperor Nepos, who ruled Dalmatia, was traitorously assassinated in Diocletian's palace at Spalato by the counts Viator and Ovida. In the following year Odoacer invaded Dalmatia, slew the murderer Ovida, and reannexed Dalmatia to the Western state. In 487 he appeared as an invader in his own native Danubian lands. War broke out between him and Feletheus, king of the Rugians. Odoacer entered the Rugian territory, defeated Feletheus, and carried him and "his noxious wife" Gisa prisoners to Ravenna. In the following year Frederick, son of the captive king, endeavoured to raise again the fallen fortunes of his house, but was defeated by Onulf, brother of Odoacer, and, being forced to flee, took refuge at the court of Theodoric the Ostrogoth, at Sistova on the lower Danube.

This Rugian war was probably an indirect cause of the fall of Odoacer. His increasing power rendered him too formidable to the Byzantine court, with whom his relations had for some time been growing less friendly. At the same time, Zeno was embarrassed by the formidable neighbourhood of Theodoric and his Ostrogothic warriors, who were almost equally burdensome as enemies or as allies. In these circumstances arose the plan of Theodoric's invasion of Italy, a plan by whom originated it would be difficult to say. Whether the land when conquered was to be held by the Ostrogoth in full sovereignty, or administered by him as lieutenant of Zeno, is a point upon which our information is ambiguous, and which was perhaps intentionally left vague by the two contracting parties, whose chief anxiety was not to see one another's faces again. The details of the Ostrogothic invasion of Italy belong properly to the life of Theodoric. It is sufficient to state here that he entered Italy in August 489, defeated Odoacer at the Isontius (Isonzo) on the 28th of August, and at Verona on the 30th of September. Odoacer then shut himself up in Ravenna, and there maintained himself for four years, with one brief gleam of success, during which he emerged from his hiding-place and fought the battle of the Addua (11th August 490), in which he was again defeated. A sally from Ravenna (10th July 491) was again the occasion of a murderous defeat. At length, the famine in Ravenna having become almost intolerable, and the Goths despairing of ever taking the city by assault, negotiations were opened for a compromise (25th February 493). John, archbishop of Ravenna, acted as mediator. It was stipulated that Ravenna should be surrendered, that Odoacer's life should be spared, and that he and Theodoric should be recognized as joint rulers of the Roman state. The arrangement was evidently a precarious one, and was soon terminated by the treachery of Theodoric. He invited his rival to a banquet in the palace of the Lauretum on the 15th of March, and there slew him with his own hand. "Where is God?" cried Odoacer when he perceived the ambush into which he had fallen. "Thus didst thou deal with my kinsmen," shouted Theodoric, and clove his rival with the broadsword from shoulder to flank. Onulf, the brother of the murdered king, was shot down while attempting to escape through the palace garden, and Thelan, his son, was not long after put to death by order of the conqueror. Thus perished the whole race of Odoacer.

Literature.—The chief authorities for the life of Odoacer are the so-called "Anonymus Valesii," generally printed at the end of Ammianus Marcellinus; the *Life of Severinus*, by Eugippius; the chroniclers, Cassiodorus and "Cuspiniani Anonymus" (both in Roncalli's collection); and the Byzantine historians, Malchus and John of Antioch. A fragment of the latter historian, unknown when Gibbon wrote, is to be found in the fifth volume of Müller's *Fragmenta Historicorum Græcorum*. Among modern students, Pallmann (*Geschichte der Völkerwanderung*, vol. ii.) has investigated the history of Odoacer the most thoroughly. (T. H.)

O'DONNELL. (1) HENRY JOSEPH (1769-1834), count of La Bisbal, a native of Spain, was descended from the O'Donnells who left Ireland after the battle of the Boyne;[1] he early entered the Spanish army, and in 1810 became general, receiving a command in Catalonia, where in that year he earned his title and the rank of field-marshal. Henry Joseph afterwards held posts of great responsibility under Ferdinand VII., whom he served on the whole with constancy; the events of 1823 compelled his flight into France, where he was interned at Limoges, and where he died in 1834. (2) LEOPOLD (1809-1867), Duke of Tetuan, Spanish general and statesman, the second son of Henry Joseph O'Donnell, was born at Santa Cruz, Teneriffe, on 12th January 1809. He fought in the army of Queen Christina, where he attained the rank of general of division; and in 1840 he accompanied the queen into exile. He failed in an attempt to effect a rising in her favour at Pamplona in 1841, but took a more successful part in the movement which led to the overthrow and exile of Espartero

[1] A branch of the family settled in Austria, and General Karl O'Donnell, count of Tyrconnel (1715-1771), held important commands during the Seven Years' War. The name of a descendant figures in the history of the Italian and Hungarian campaigns of 1848 and 1849.

in 1843. From 1844 to 1848 he served the new Government in Cuba; after his return he entered the senate. In 1854 he became war minister under Espartero, and in 1856 he plotted successfully against his chief, becoming head of the cabinet from the July revolution until October. This rank he again reached in July 1858; and in December 1859 he took command of the expedition to Morocco, and received the title of duke after the surrender of Tetuan. Quitting office in 1863, he again resumed it in June 1865, but was compelled to resign in favour of Narvaez in 1866. He died at Bayonne on 5th November 1867.

ODORIC (*c.* 1286-1331), styled of Pordenone, one of the notable travellers to the farther East in the Middle Ages, and a *Beatus* of the Roman Church, was born at Villa Nuova, a hamlet near the town of Pordenone in Friuli, in or about 1286, and, according to ecclesiastical biographers, in early years took the vows of the Franciscan order and joined their convent at Udine, the capital of Friuli. Under CHINA (vol. v. p. 628) the remarkable opening of communication, both commercial and ecclesiastical, with that country during the first half of the 14th century has been spoken of. There had arisen also during the latter half of the 13th century an energetic missionary action, extending all over the East, on the part of both the new orders of Preaching and Minorite (or Dominican and Franciscan) Friars, and houses of those orders, of the last especially, became established in Persia, in what is now southern Russia, in Tartary, and in China.

Friar Odoric was despatched to the East about 1316-18, and did not return till near 1330, but, as regards intermediate dates, all that we can deduce from his narrative or other evidence is that he was in western India soon after 1321, and that he spent three years in China between 1322 and 1327. His route to the East lay by Constantinople and Trebizond to Erzeroum, and thence to Tabríz and Sultániya, in all of which places the order had houses. From Sultániya he proceeded by Kashán and Yezd, and turning thence followed a somewhat devious route by Persepolis, Shiráz, and Baghdád to the Persian Gulf. At Ormuz he embarked for India, landing at Tana, still the chief station of the island of Salsette, and which was then one of the chief ports of western India. At this city four brethren of his order, three of them Italians and the fourth a Georgian, had shortly before met death at the hands of the Mohammedan governor, who held the place under the dominion of the sovereign of Delhi (then Ghaiássuddín Tughlak). The bones of the martyred friars had been collected by Friar Jordanus of Severac, a Dominican, who carried them to Supera—the *Suppara* of the ancient geographers, near the modern Bassein, about 26 miles north of Bombay—and buried them there. Odoric tells that he disinterred these relics and carried them with him on his farther travels. In the course of these he visited Malabar, touching at Pandaráni (20 miles north of Calicut), at Cranganore, and at Quilon, proceeding thence, apparently, to Ceylon and to the shrine of St Thomas at Mailapur near Madras. From India he sailed in a Chinese junk to Sumatra, visiting various ports on the northern coast of that island, then Java, the coast (it would seem) of Borneo, Champa (South Cochin China), and Canton, at that time known to western Asiatics as *Chín-Kolón* or Great China (Maháchín). Thence he went on to the great ports of Fuhkeen, at one of which, Zayton or Chwanchow (see CHINCHEW, vol. v. p. 673), he found two houses of his order; in one of these he deposited the bones of the brethren who had suffered in India. From Fu-chau he struck across the mountains into Che-keang and visited Hang-chow, then renowned under the name of *Cansay* ("King-sze," or royal residence) as one of the greatest cities in the world, of the splendours of which Marco Polo, Ibn Batuta, and others have given such notable details. Passing northward by Nan-king and crossing the Great Kiang, Odoric embarked on the Great Canal and travelled to CAMBALUC or Peking, where he remained for three years, attached, no doubt, to one of the churches founded by Archbishop John of Monte Corvino, at this time in extreme old age. Turning westward in the neighbourhood of the Great Wall and through Shensi, the adventurous traveller entered Tibet, and appears to have visited Lhasa. But no distinct indication of his homeward route is given, though it may be gathered from fragmentary notices that he passed through Khorasan, and so probably by Tabríz to Europe, reaching Venice in the end of 1329 or beginning of 1330. During a part at least of these long journeys the companion of Odoric was Friar James, an Irishman, as appears from a record in the public books of Udine, showing that shortly after Odoric's death a present of two marks was made to this Irish friar, *Socio beati Odorici, amore Dei et Odorici.* Shortly after his return Odoric betook himself to the Minorite house attached to St Antony's at Padua, and it was there that in May 1330 he related the story of his travels, which was taken down in homely Latin by Friar William of Solagna. Travelling towards the papal court at Avignon, Odoric fell ill at Pisa, and, turning back to Udine, the capital of his native province, died in the convent there, 14th January 1331. The fame of his vast journeys appears to have made a much greater impression on the laity of his native territory than on his Franciscan brethren. The latter were about to bury him without delay or ceremony, but the "gastald" or chief magistrate of the city interfered and appointed a public funeral; rumours of his wondrous travels, and of posthumous miracles were diffused, and excitement spread like wildfire over Friuli and Carniola; the ceremony had to be deferred more than once, and at last took place in presence of the patriarch of Aquileia and all the local dignitaries. The sanctity of Odoric was now fully recognized, and was taken up at last by his own community, who employed an eminent preacher to declaim to the people the history and pious deeds of this brother, whom they probably had regarded till now only as an eccentric, who told questionable stories about the Grand Cham and islands of the anthropophagi. Popular acclamation made him an object of devotion, the municipality erected a noble shrine for his body, his fame as saint and traveller had spread far and wide before the middle of the century, but it was not till four centuries later (1755) that the papal authority formally sanctioned his beatification. A bust of Odoric was set up at Pordenone in 1881.

The numerous MSS. of Odoric's narrative that have come down to our time (upwards of forty are known), and chiefly from the 14th century, show how speedily and widely it acquired popularity. It does not deserve the charge of general mendacity brought against it by some, though the language of other writers, who have spoken of the traveller as a man of learning, is still more injudicious. Like most of the mediæval travellers, he is indiscriminating in accepting strange tales; but, whilst some of these are the habitual stories of the age, many particulars which he relates attest the genuine character of the narrative, and some of those which Tiraboschi and others have condemned as mendacious interpolations are the very seals of truth. Odoric's credit was not benefited by the liberties which Sir John Mandeville took with it. The substance of that knight's alleged travels in India and Cathay is stolen in bulk from Odoric, though largely amplified with fables from other sources and from his own invention, and garnished with his own unusually clear astronomical notions. We may indicate a few passages which stamp Odoric as a genuine and original traveller. He is the first European who distinctly mentions the name of Sumatra. The cannibalism and community of wives which he attributes to certain races of that island do certainly belong to it, or to islands closely adjoining. His description of sago in the archipelago is not free from errors, but they are the errors of an eye-witness. In China his mention of Canton by the name of Chín-Kalán, his description of the custom of fishing with tame cormorants, of the habit of letting the finger-nails grow extravagantly, and of the compression of women's feet, as well as of the division of the empire into twelve

provinces, with four chief ministers, are all peculiar to him among the travellers of that age; Marco Polo omits them all.

The narrative was first printed at Pesaro in 1513, in what Apostolo Zeno calls *lingua inculta e rozza*, probably, therefore, in a Venetian dialect. Ramusio's collection first contains it in the 2d vol. of the 2d edition (1574), in which are given two versions, differing curiously from one another, but without any prefatory matter or explanation. Another (Latin) version is given in the *Acta Sanctorum* (Bollandist) under 14th January. The curious discussion before the papal court respecting the beatification of Odoric forms a kind of blue-book issued *ex typographia rev. cameræ apostolicæ*, Rome, 1755. Professor Kunstmann of Munich devoted one of his valuable papers to Odoric's narrative (*Histor.-Polit. Blättern von Phillips und Görres*, vol. xxxviii.). The collection called *Cathay and the Way Thither*, by Colonel Yule (Hak. Soc., 1866), contains a careful translation and commentary, &c. A new edition in Italian has been recently issued in Italy, but it is not of value. (H. Y.)

ODYSSEUS is of all the Greek heroes the most typical representative of the Greek race. The quality on which he prides himself (*Od.*, ix. 19) is his cunning and ready wit; his inventive genius never fails in the greatest danger. But his cunning is not of the narrow kind that is incompatible with real wisdom; he is not troubled by scruples, but he uses nobly and liberally a power that he has acquired by craft; he is fond of adventure and yet full of prudence, very cautious and yet in case of need brave. It is a character that in the hands of Homer is very fine, but which in those of almost all other writers becomes repulsive. He was son of Laertes and Anticleia, and king of Ithaca, a small rocky island on the western side of Greece. He married Penelope, but very soon after his marriage he was summoned to the Trojan war. Unwilling to go, he feigned madness, yoked an ox and a horse together, but Palamedes discovered his deceit by means of his care for his infant child Telemachus; afterwards Odysseus revenged himself by compassing the death of Palamedes. Obliged to go to the war, he distinguished himself as the wisest councillor of the Greeks, and finally, the capture of Troy, which the bravery of Achilles could not accomplish, was attained by Odysseus's stratagem of the wooden horse. After the death of Achilles the Greeks adjudged his armour to Odysseus as the man who had done most to make the war successful. When Troy was captured he set sail for Ithaca, but was carried by unfavourable winds to the coast of Africa. After encountering many adventures in all parts of the unknown seas, among the lotus-eaters and the Cyclopes, in the isles of Æolus and Circe and the perils of Scylla and Charybdis, among the Læstrygons, and even in the world of the dead, having lost all his ships and companions, he barely escaped with his own life to the island of Calypso, where he was detained eight years, an unwilling lover of the beautiful nymph. Then at the command of Zeus he was sent homewards, but was again wrecked on the island of Phæacia, whence he was conveyed to Ithaca in one of the wondrous Phæacian ships. Here he found that a host of suitors, taking advantage of the youth of his son Telemachus, were wasting his property and trying to force Penelope to marry one of them. The stratagems and disguises by which he with a few faithful friends slew the suitors are described at length in the *Odyssey*.

There is no doubt that the personality of Odysseus developed out of some germ in primitive religious myth; but it is almost hopeless to seek for the early form, so completely has it been transformed. In many heroes of poetry and mythology the chief interest lies in tracing the growth of the conception from the divine form of early religion to the Greek hero of poetry; but in the case of Odysseus the supreme interest attaches to the perfect form as it appears in Homer, the typical representative of the old sailor-race whose adventurous voyages educated and moulded the Hellenic race. The period when the character of Odysseus grew among the Ionian bards was when the Ionian ships were beginning to penetrate to the farthest shores of the Black Sea, and to the western side of Italy, but when Egypt had not yet been freely opened to foreign intercourse by Psammetichus and his successors. The tale of Odysseus gives us the form in which the voyages, the perils, the strange races of foreign lands, and the rich spoils of the sailors were mirrored in the minds of the nation and sung by its poets.

ŒCOLAMPADIUS,[1] JOHN (1482-1531), was born at Weinsberg, a small town in the north of the modern kingdom of Würtemberg, but then belonging to the Palatinate. He went to school at Weinsberg and Heilbronn, and at seventeen entered the university of Heidelberg, where he took his bachelor's degree in 1503. He seems at first to have intended to study for the profession of law, and went to Bologna, but soon returned to Heidelberg and betook himself to theology. He became a zealous student of the new learning and passed from the study of Greek to that of Hebrew. He went from Heidelberg to Tübingen, and thence to Stuttgart, making the acquaintance of Erasmus, Hedio, and Reuchlin, and after some earlier essays in preaching became pastor at Basel in 1515, serving under Christopher von Uttenheim, the evangelical bishop of Basel. From the beginning the sermons of Œcolampadius had "Christ the crucified" as their theme, and his first reformatory zeal showed itself in a protest against the introduction of legends of the saints into Easter sermons. While in Basel, preaching did not absorb all his energies; he was in daily intercourse with learned friends at the university, and pursued his literary researches and humanist studies. In 1518 he published his *Greek Grammar*. The same year he was asked to become pastor in the high church in Augsburg. Germany was then ablaze with the questions raised by Luther's theses, and his introduction into this new world seems to have compelled Œcolampadius to severe self-examination, which ended in his entering a convent and becoming a monk. A short experience sufficed to convince him that the monkish was not the ideal Christian life (*amisi monachum, inveni Christianum*), for in the beginning of 1522 he became private chaplain to the famous Franz von Sickingen. He left his service in the end of the same year and returned to Basel. Zwingli's famous disputation at Zurich (in 1523) fired the minds of many in Switzerland, and among others stirred Œcolampadius to make a more decided stand for reformation. He began to imitate Zwingli and preach Reformed doctrine. To his surprise he found that the humanists of the university did not countenance him in his zeal for evangelical truth. When "disputations" were held, they prohibited the students and teachers from attending. After more than a year of earnest preaching, after four public disputations had been held, in which the popular verdict had been given in favour of Œcolampadius and his friends, the authorities of Basel began to see the necessity of some reformation. They began with the convents, and Œcolampadius was able to refrain in public worship on certain festival days from some practices he believed to be superstitious. Basel was slow to accept the Reformation; the news of the Peasants' War and the inroads of Anabaptists prevented progress; but at last, in 1525, it seemed as if the authorities were resolved to listen to schemes for restoring the purity of worship and teaching. In the midst of these hopes and difficulties Œcolampadius married, in the beginning of 1528, Wilibrandis Rosenblatt, the widow of Ludwig Keller, who proved to be *non rixosa vel garrula vel vaga*, he says, and made him a good wife. After his death she married Capito, and, when Capito died, Bucer. She died in 1564. In 1528 the mass and image worship were at

[1] Hussgen or Heussgen, changed to Hausschein, and then into the Greek equivalent.

last abolished by authority, and Œcolampadius's five years' struggle was ended. He lived on, growing in influence in Basel and throughout south Germany, three years longer, and died in November 1531.

Œcolampadius was not a great theologian, like Luther, Zwingli, or Calvin, and yet he was a trusted theological leader. With Zwingli he represented the Swiss views at the unfortunate conference at Marburg, and had proved himself, by his defence of Zwingli's doctrine of the Lord's Supper against both Brenz and Luther, an able controversialist. He was a man of very wide sympathies. His readiness to sympathize with the early Reformatory movements in France and his eager welcome of the Waldenses were of great value to the Swiss Church.

Compare Herzog, *Leben Joh. Œcolampads u. die Reformation der Kirche zu Basel*, 1843; Hagenbach, *Johann Œcolampad u. Oswald Myconius, die Reformatoren Basels*, 1859.

OEDENBURG (Hungarian, *Sopron*), one of the oldest and most prepossessing towns in Hungary, the chief place of a district of its own name, lies 3 miles to the west of the Lake of Neusiedl and 35 miles to the south-south-east of Vienna. It possesses several churches (one of which was built with the contents of a Turkish military chest found buried here), three convents, a Protestant lyceum with a theological department, a Roman Catholic gymnasium, several other schools and charitable institutions, a museum, and a theatre. The inhabitants, most of whom are of German descent, are mainly engaged in making wine, of which the district yields a quality little inferior to Tokay. The crystallized fruits of Oedenburg form a well-known article of commerce; and a trade in grain and manufactures of beetroot-sugar, starch, and cloth are also carried on. Large cattle-markets are held here. The population in 1880 was 23,222.

Oedenburg, the Roman station Sopronium, was created a royal free town in the 11th century in return for help afforded to the king of Hungary against the Bulgarians. In 1619 it was pillaged by Bethlen Gabor. At a diet held here in 1681 the Hungarian Protestants presented the so-called "Oedenburg Articles," claiming the restitution of their churches and estates. The province of Oedenburg is rich in corn, fruit, cattle, and coal.

ŒDIPUS, a Theban hero, is placed by genealogists among the descendants of Cadmus. His father Laius ordered him to be exposed as soon as he was born; he grew up ignorant of his parentage, and meeting his father once in a narrow way he quarrelled with him and slew him. The country was ravaged by a monster, the Sphinx; Œdipus by his cunning solved the riddle that the Sphinx proposed to its victims, freed the country, and married his own mother, Jocaste, or, as Homer calls her, Epicaste. In the *Odyssey* it is said that the gods disclosed the impiety. Epicaste hanged herself, and Œdipus lived as king in Thebes tormented by the Erinnyes of his mother. In the tragic poets the tale takes a different form. Œdipus fulfils an ancient prophecy in killing his father; he is the blind instrument in the hands of fate. The further treatment of the tale by Æschylus is unknown. Sophocles describes in his *Œdipus the King* how Œdipus was resolved to pursue to the end the mystery of the death of Laius, and thus unravelled the dark tale, and in horror put out his own eyes. The sequel of the tale is told in *Œdipus at Colonus*. Banished from the land by his sons, he is tended by the loving care of his daughters. He comes to Attica and dies in the grove of the Eumenides at Colonus, in his death welcomed and pardoned by the fate which had pursued him throughout his life. This view of the myth, which reads in it a parable of the mystery of life, of the overwhelming might of fate and the weakness of man, of the final reconciliation of discord in death, is due to the tragic poets, is unknown in the epic poets, and is still more foreign to the primitive mythic form, where Œdipus and his father embody the vicissitudes of the annual life of nature: the son, the young year, slays his father, the old year, is wedded to his own mother, but finally loses his eyes, his light, and his life. The winter king is a god who slays his own father; this is a trait that occurs time after time in mythology.

OEHLENSCHLÄGER, Adam Gottlob (1779-1850), the greatest of modern Danish poets, was born in Vesterbro, a suburb of Copenhagen, on the 14th of November 1779. His father, a Schleswiger by birth, was at that time organist to, and later on became keeper of, the royal palace of Frederiksberg; he was a very brisk and cheerful man. The poet's mother, on the other hand, who was partly German by extraction, suffered from depressed spirits, which afterwards deepened into melancholy madness. Adam and his sister Sofia were allowed their own way throughout their childhood, and were taught nothing, except to read and write, until their twelfth year. At the age of nine Adam began to make fluent verses. Three years later, while walking in Frederiksberg Gardens, he attracted the notice of the poet Edvard Storm, and the result of the conversation was that he received a nomination to the college called "Posterity's High School," an important institution of which Storm was the principal. Storm himself taught the class of Scandinavian mythology, and thus Oehlenschläger received his earliest bias towards the poetical religion of his ancestors. Most other branches of study the boy continued to neglect, and thought most about the romances and dramas which he proposed to write. He was confirmed in 1795, and was to have been apprenticed to a tradesman in Copenhagen. To his great delight there was a hitch in the preliminaries, and he returned to his father's house. He now, in his eighteenth year, suddenly took up study with great zeal, but soon again abandoned his books for the stage, where a small position was offered him. In 1797 he actually made his appearance on the boards in several successive parts, but soon discovered that he possessed no real histrionic talent, even though he was trained by the great actor Michael Rosing. The brothers Oersted, the eminent savants, with whom he had formed an intimacy fruitful of profit to him, persuaded him to quit the stage, and in 1800 he entered the university of Copenhagen as a student. He was doomed, however, to disturbance in his studies, first from the death of his mother, next from his inveterate tendency towards poetry, and finally from the attack of the English upon Copenhagen in April 1801, which, however, inspired a dramatic sketch which is the first thing of the kind by Oehlenschläger that we possess. His promise was already widely felt, and, even in 1800, Baggesen, in departing for Germany, had publicly invested the youth with the laurel that he himself was resigning. It was in the summer of 1802, when Oehlenschläger had an old Scandinavian romance, as well as a volume of lyrics, in the press, that the young Norse philosopher, Henrik Steffens, came back to Copenhagen after a long visit to Schelling in Germany full of new romantic ideas. His lectures at the university, in which Goethe and Schiller were for the first time revealed to the Danish public, created a great sensation. Steffens and Oehlenschläger met one day at Dreier's Club, and after a conversation of sixteen hours, which has become famous in the history of anecdote, the latter went home, suppressed his two coming volumes, and wrote at a sitting his splendid poem *Guldhornene*, in a manner totally new to Danish literature. The result of his new enthusiasm speedily showed itself in a somewhat hasty volume of poems, published in 1803, now chiefly remembered as containing the lovely piece called *Sanct-Hansaften-Spil*. The next two years saw the production of several exquisite works, in particular *Thors Reise til Jotunheim*, the charming poem in hexameters called *Langelandsreisen*, and the bewitching piece of fantasy *Aladdin's Lampe*. At the age of twenty-six Oehlenschläger was now universally recognized, even by the opponents of the romantic revival, as the leading poet of Denmark. He found no difficulty in obtaining

a grant for foreign travel from the Government, and he left his native country for the first time, joining Steffens at Halle in August 1805. Here he wrote the first of his great historical tragedies, *Hakon Jarl*, which he sent off to Copenhagen, and then proceeded for the winter months to Berlin, where he associated with Humboldt, Fichte, and the leading men of the day. In the spring of 1806 he went on to Weimar, where he spent several months in daily intercourse with Goethe. The autumn of the same year he spent with Tieck in Dresden, and proceeded in December to Paris. Here he resided eighteen months and wrote his three famous masterpieces, *Baldur hin Gode*, *Palnatoke* (1807), and *Axel og Valborg* (1808). In July 1808 he left Paris and spent the autumn and winter in Switzerland as the guest of Madame de Staël-Holstein at Coppet, in the midst of her famous circle of wits. In the spring of 1809 Oehlenschlager went to Rome to visit Thorwaldsen, and in his house wrote his tragedy of *Correggio*, in German; he translated this into Danish the following year. After an absence of nearly five years he hurriedly returned to Denmark in the spring of 1810, partly to take the chair of æsthetics at the university of Copenhagen, partly to marry the sister-in-law of Rahbek, to whom he had been long betrothed. His first course of lectures dealt with his Danish predecessor Evald, the second with Schiller. From this time forward his literary activity became very great; in 1811 he published the Oriental tale of *Ali og Gulhyndi*, and in 1812 the last of his great tragedies, *Stærkodder*. From 1814 to 1819 he, or rather his admirers, were engaged in a long and angry controversy with Baggesen, who represented the old didactic school. This contest seems to have disturbed the peace of Oehlenschläger's mind, and to have undermined his genius. His talent may be said to have culminated in the glorious cycle of verse-romances called *Helge*, published in 1814. The tragedy of *Hagbarth og Signe*, 1815, showed a distinct falling-off in style. In 1817 he went back to Paris, and published *Hroars Saga* and the tragedy of *Fostbrödrene*. In 1818 he was again in Copenhagen, and wrote the idyll of *Den lille Hyrdedreng* and the Eddaic cycle called *Nordens Guder*. His next productions were the tragedies of *Erik og Abel* (1820) and *Væringerne i Miklagaard* (1826), and the epic of *Hrolf Krake* (1829). It was in the last-mentioned year that, being in Sweden, Oehlenschläger was publicly crowned with laurel in front of the high altar in Lund cathedral by Bishop Esaias Tegnér, as the "Scandinavian King of Song." His last volumes were *Tordenskjold* (1833), *Dronning Margrethe* (1833), *Sokrates* (1835), *Olaf den Hellige* (1836), *Knud den Store* (1838), *Dina* (1842), *Erik Glipping* (1843), and *Kiartan og Gudrun* (1847), none of which, with the exception, perhaps, of *Dina*, can in any way be said to be worthy of his early reputation. On his seventieth birthday, 14th November 1849, a public festival was arranged in his honour, and he was decorated by the king of Denmark under circumstances of great pomp. Just two months later, on the 20th of January 1850, he sank, conscious to the last, and was buried in the cemetery of Frederiksberg.

With the exception of Holberg, there has been no Danish writer who has exercised so wide an influence as Oehlenschläger. His great work was to awaken in the breasts of his countrymen an enthusiasm for the poetry and religion of their ancestors, and this he performed to so complete an extent that his name remains to this day synonymous with Scandinavian romance. He supplied his countrymen with romantic tragedies at the very moment when all eyes were turned to the stage, and when the old-fashioned pieces were felt to be inadequate. His plays, partly, no doubt, in consequence of his own early familiarity with acting, fulfilled the stage-requirements of the day, and were popular beyond all expectation. Several of them still keep the stage in spite of their rhetoric. The earliest are the best,—Oehlenschlager's dramatic masterpiece being, without doubt, his first tragedy, *Hakon Jarl*. In his poems and plays alike his style is limpid, elevated, profuse; his flight is sustained at a high pitch without visible excitement. His fluent tenderness and romantic zest have been the secrets of his extreme popularity. Although his inspiration came from Germany, he is not much like a German poet, except when he is consciously following Goethe; his analogy is much rather to be found among the English poets, his contemporaries. His mission towards antiquity reminds us of Scott, but he is, as a poet, a better artist than Scott; he has sometimes touches of exquisite diction and of overwrought sensibility which recall Coleridge to us. In his wide ambition and profuseness he possessed some characteristics of Southey, although his style has far more vitality. With all his faults he was a very great writer, one of the principal pioneers of the romantic movement in Europe, and he will probably not cease to retain the position which he won so easily at the summit of the Scandinavian Parnassus. (E. W. G.)

OELS, the chief town of a circle in Prussian Silesia, and the capital of a mediatized principality of its own name, lies in a sandy plain on the Oelsa, 18 miles to the north-east of Breslau. The prince's château, dating from 1558, contains a good library and a collection of pictures. The Schlosskirche was originally built about 980. The other buildings are unimportant. The inhabitants, numbering 10,157 in 1880, are chiefly engaged in making shoes and growing vegetables for sale at Breslau. There is also a manufactory of agricultural implements, and a trade is carried on in grain and flax.

The town of Oels was founded about 940, and appears as the capital of an independent principality at the beginning of the 14th century. The principality, with an area of 750 square miles and about 150,000 inhabitants, passed through various hands and was finally inherited by the ducal family of Brunswick in 1792. The present proprietor is the reigning duke of Brunswick.

See W. Hausler, *Geschichte des Fursienthums Oels* (Breslau, 1883)

ŒNANTHIC ACID AND ETHER. Liebig and Pelouze, by distilling large quantities of wine, obtained from the very last fractions of the distillate an oil which in a very high degree exhibited the generic smell common to all wines,—the smell which a small remnant of any kind of wine left in an open bottle exhibits after the "bouquet" is gone. They recognized the oil as the ethyl-ether of a particular acid of the composition $(C_{14}H_{26}O_3)H_2$, which they called "œnanthic acid." An oil similar to Liebig and Pelouze's œnanthic ether was isolated by Wöhler from quince-peel. Liebig and Pelouze's results were called in question by Delffs, who by experiments of his own arrived at the result that their œnanthic acid is identical with pelargonic, $C_9H_{17}O_2 . H$, which latter is known as a component of the volatile oil of *Pelargonium roseum*. A. Fischer examined an "œnanthic ether" manufactured by Lichtenberger at Hambach in the Rhenish Palatinate, and found it to be a mixture of the ethyl-ethers of caprylic and capric acids, $C_8H_{16}O_2$ and $C_{10}H_{20}O_2$, and fatty acids higher than capric. The general impression amongst chemical wine-specialists seems to be that Liebig and Pelouze's œnanthic acid was a mixture of capric, caprylic, and other fatty acids. The notion of œnanthic acid must not be mixed up with that of œnanthylic acid, $C_7H_{13}O_2 . H$, the acid of primary heptyl-alcohol, $C_7H_{16}O$. The aldehyde $C_7H_{14}O$, intermediate between the two, is procured by the destructive distillation of castor oil, and from it the acid is easily prepared by oxidation with dilute chromic acid.

ŒNOMAUS was king of Olympia, where his wooden house was still shown in the Altis, the sacred precinct, when Pausanias visited it. It was fated that he should be slain by the husband of his daughter Hippodamia. His father, the god Ares-Hippios, gave him winged horses swift as the wind, and he promised his daughter to the man who could outstrip him in the chariot race; those suitors who were beaten died by his hand. Pelops, by the treachery of Myrtilus, the charioteer of Œnomaus, won the race and married Hippodamia. Pelops is conceived as a stranger from Asia Minor, and Œnomaus is obviously the representative of a race of Ares-worshippers who were conquered by, or amalgamated with, an immigrant race, who brought

with them the new religion of Zeus, but who kept up the old worship of Ares in the country where they settled.

OESEL, one of the largest islands in the Baltic, forming with Abro, Mohn, Runo, &c., a district of the Russian government of Livonia, lies across the mouth of the Gulf of Riga, between 57° 55′ and 58° 40′ N. lat., has a length from south by west to north by east of about 45 miles, and according to Strelbitsky contains an area of 1010 square miles. It is separated from Courland to the south by the Strait of Dosmesnes, from the island of Dagö to the north by the Söla Sound, and from the smaller island of Mohn on the north-east by the Little Sound. Its undulating surface, well watered by numerous streams, and consisting mainly of clay and disintegrated limestone, is largely occupied by woodland and pasture, but also allows the cultivation of considerable quantities of grain, flax, hemp, and potatoes. The coasts are bold and steep, and, especially towards the north and west, form precipitous limestone cliffs. Like those of Shetland, the Oesel ponies are prized for their smallness. The population, numbering 50,566 in 1870, is mainly Protestant in creed, and, with the exception of the nobility, the clergy, and some of the townsfolk, Esthonian by race. The chief town, Arensburg (Esthonian, *Kurre Saare*), on the south coast at the mouth of the Peddus, is a place of from 3000 to 4000 inhabitants, with two churches (a Greek and a Lutheran), two hospitals, an orphanage, and a trade in grain, potatoes, whisky, and fish.

Oesel at an early period belonged to the Teutonic knights, and was governed by its bishops till 1561, when it passed into the hands of the Danes. By them it was surrendered to the Swedes by the peace of Bromsebro (1645), and, along with Livonia, it was united to Russia in 1721. Arensburg, dating as a castle from the 14th century, became a town in 1563.

OFEN. See BUDA, vol. iv. p. 423.

OFFENBACH, the principal manufacturing town in the grand duchy of Hesse-Darmstadt, lies on the left bank of the Main, 5 miles above Frankfort. The most interesting building in the town is the old Renaissance château of the counts of Isenburg, while the most conspicuous modern edifices are the five churches, the synagogue, the new residence of the Isenburg family, and the town-hall. The manufactures of Offenbach are of the most varied description, including carriages, machinery, hardwares, chemicals, aniline dyes, soap, perfumery, candles, chicory, gingerbread, tobacco and cigars, shoes, hats, felt goods, wax-cloth, paper, varnish, white lead, types, canvas, and woollen cloth. Its characteristic industry, however, is the manufacture of portfolios, pocket-books, albums, and other fancy goods in leather, which are largely exported to England, the United States, and other countries. The population in 1880 was 28,449, including 17,566 Protestants and 8782 Roman Catholics.

The earliest mention of Offenbach is in a document of 970. In 1456 it came into the possession of the imperial counts of Isenburg, and in 1816, on their mediatization, was assigned to Hesse. It owes its prosperity partly to the fact that it became the residence of the Isenburg family in 1685, but mainly to the industry of the French Protestant refugees who settled here at the end of the 17th and the beginning of the 18th century.

OFFENBACH, JACQUES (1819-1880), the inventor of the latest form of the modern *opéra bouffe*, was born at Cologne, of Jewish parents, 21st June 1819. His talent for music was developed at a very early age; and in 1833 he was sent to Paris to study the violoncello at the conservatoire, where, under the care of Professor Vaslin, he became a fairly good performer, notwithstanding his utter want of that earnestness which alone can make a true artist. In 1834 he was admitted into the orchestra of the Opéra Comique as a "ripieno" violoncellist; and here his unrivalled tact and natural quickness of perception enabled him to acquire an amount of experience which he was not slow to turn to profitable account. His next appointment was that of conductor at the Théâtre Français, where, in 1848, he made his first success as a composer in the "Chanson de Fortunio," in Alfred de Musset's play *Le Chandelier*. From this time forward his life became a ceaseless struggle for the attainment of popularity. His power of production was inexhaustible; and, since he was ready to repeat himself without scruple whenever it answered his purpose to do so, the demand upon his ideas was invariably met with a rapidity which fairly astonished both theatrical managers and the general public. His first complete work, *Pepito*, was produced at the Opéra Comique in 1853. This was soon followed by a crowd of dramatic trifles, which daily gained in favour with Parisian audiences, and eventually effected a complete revolution in the popular taste of the period. Encouraged by these early successes, Offenbach now boldly undertook the delicate task of entirely remodelling both the form and the style of the light musical pieces which have so long been welcomed with acclamation by the frequenters of the smaller theatres in Paris. With this purpose in view he obtained a lease of the Théâtre Comte in the Passage Choiseul, re-opened it under the title of the Bouffes Parisiens, and night after night attracted crowded audiences by a succession of brilliant trifles which never failed to make their mark, though not one of them possessed substance enough to enable it to retain its vitality after the appearance of its successor upon the stage. Beginning with *Les Deux Aveugles* and *Le Violoneux*, the series was continued with almost unexampled rapidity, until, in 1867—twelve years after the opening of the theatre—its triumph culminated in *La Grande Duchesse de Gérolstein*, perhaps the most popular opéra bouffe that ever was written, not excepting even his *Orphée aux Enfers*, produced in 1858. From this time forward the success of Offenbach's pieces became an absolute certainty. He never failed. Without a trace of true genius or a thought of reverence for art, he possessed a talent so brilliant and a facility of invention so prolific that, in place of following the public taste, as he had so cleverly done at the outset of his career, he was able to lead it whither he would; and the new form of opéra bouffe, which he had gradually endowed with as much consistency as it was capable of assuming, was accepted as the only one worth cultivating. That it should live is simply impossible. It has, indeed, found imitators in Lecocq and other aspirants of a younger generation; and some of these have attained successes not much less brilliant than those of Offenbach himself. But to be really enduring an art-form must be based upon some stronger principle than a mere desire for the attainment of popular favour; and so far is this from being the case with what is now universally accepted as the genuine opéra bouffe that it would be impossible to strain the point so far as to admit its connexion with any form of art whatever. But no artistic consideration dimmed the brilliancy of Offenbach's success. His theatre continued to flourish, and his works found their way to every town in Europe in which a theatre existed. Their want of refinement formed no obstacle to their popularity, and perhaps even contributed to it. In twenty-five years he produced no less than sixty-nine complete dramatic works, some of which were in three or even in four acts. Among the latest of these were *Le Docteur Ox*, founded on a story by Jules Verne, and *La Boite au Lait*, both produced in 1877, and, though not among his brightest triumphs, sufficiently successful to show that the reign of his popularity has not yet come to an end. Offenbach died in 1880.

OGAM. See CELTIC LITERATURE, vol. v. p. 306.

OGDEN, a flourishing city of the United States, in

Weber county, Utah, 37 miles by rail north of Salt Lake City, at the confluence of the Weber and Ogden rivers. It is one of the most important railway junctions of the Western States; the Union Pacific, the Central Pacific, and the Utah Central Railroads, as well as a line which will ultimately join the Northern Pacific at Garrison, all meet at this point. The ground-plan of the city is spacious, the drainage good, and the climate exceedingly healthy. In manufactures and general industry it bids fair to rival Salt Lake City. Conspicuous among its buildings are the court-house with its white cupola, and the central school, which is one of the best in Utah. The population was 3127 in 1870, and 6069 in 1880.

OGDENSBURG, a city and port of entry of the United States, in St Lawrence county, New York, on the St Lawrence river, at the mouth of the Oswegatchie, 72 miles below Lake Ontario. It is an important railway junction (the terminus of the Ogdensburg and Lake Champlain, the Utica and Black River, and the Rome, Watertown, and Ogdensburg Railroads), and the headquarters of the Northern Transportation Company's line of steamers; and ferry steamers connect it with Prescott on the Canadian side of the river. Ogdensburg is regularly laid out, and shade-trees are so numerous that it is popularly called "Maple City." Among its buildings that used by the United States post-office and courts and the great Roman Catholic church of St Jean Baptiste are of some note. A very extensive trade is carried on in timber and flour. The population was 7409 in 1860, 10,076 in 1870, and 10,341 in 1880.

The site of Ogdensburg was first occupied by the Indian settlement of La Presentation founded by Abbé Piquet for the Christian converts of the Five Nations. Garrisoned by the British in 1776, the fort continued to be held by them after the revolution till 1796 (Jay's treaty). In 1812 it was attacked and in 1813 captured by a British force; and again in 1838, having become a rallying point for the Canadian malcontents under Von Schultze, it was regularly besieged and taken. The village was incorporated in 1817, and named after Samuel Ogden, the proprietor. The city charter dates from 1868.

OGLETHORPE, JAMES EDWARD (1696-1785), general, the founder of the State of Georgia, was born in London 21st December 1696, the son of Sir Theophilus Oglethorpe of Godalming, Surrey. He entered Corpus Christi College, Oxford, in 1714, but in the same year joined the army of Prince Eugène. Through the recommendation of the duke of Marlborough he became aide-de-camp to the prince, and he served with distinction in the campaign against the Turks, 1716-17, more especially at the siege and capture of Belgrade. After his return to England he was in 1722 chosen member of parliament for Hazlemere. He devoted much attention to the improvement of the circumstances of poor debtors in London prisons; and for the purpose of providing an asylum for persons who had become insolvent, and for oppressed Protestants on the Continent, he projected the settlement of a colony in America between Carolina and Florida. A full account of the enterprise and the subsequent relation of Oglethorpe to the colony will be found in the article GEORGIA, vol. x. p. 437. In 1745 Oglethorpe was promoted to the rank of major-general. His conduct in connexion with the Scottish rebellion of that year was the subject of inquiry by court-martial, but he was acquitted. In 1765 he was raised to the rank of general. He died at Cranham Hall, Essex, 1st July 1785.

OGOWAY, or OGOWE (*Ogowai, Ogobai*), a river of West Africa which falls into the Atlantic in the neighbourhood of 1° S. lat., or 400 miles north of the mouth of the Congo. The extent of its delta (70 to 80 miles from north to south), and the immense volume of water which it brings down when in flood, gave origin to the belief that it must either be a bifurcation of the Congo or one of the leading arteries of the continent. The former view was set aside by the fact that the two rivers did not rise at the same season of the year; but so recently as 1876 Czerny advocated the identity of the Ogoway with Schweinfurth's famous Uelle (Welle), with Nachtigal's Bahr-Kuta, and with Barth's river of Kubanda, thus taking it right across to the neighbourhood of the Nile basin. It appears, however, that the head-streams of the Ogoway rise in the hilly country about 200 or 300 miles from the coast of the Atlantic (though the actual course of the river is 500 to 600 miles), and its extraordinary volume is to be explained by their draining an extensive tract on both sides of the equator which is deluged with tropical rains. Savorgnan de Brazza claims to have reached (1882) the sources of the river in a rugged, sandy, and almost treeless plateau, which forms the watershed between its basin and that of the Congo, whose main stream is only 140 miles distant. Cutting its way athwart the gneiss and schists of the various ranges of the Sierra Complida, the main stream of the Ogoway (often called the Okanda from one of the tribes on its banks) is interrupted with cataracts and rapids (at Fare, 26 feet, and Dume, for example) till within a comparatively short distance from the confluence with its principal left-hand affluent, the Ngunie, in 0° 35′ S. lat. and 10° 25′ E. long. Even in the upper part of its course, however, it often attains a great width, and below this confluence it spreads out into an average of 8000 feet, at the same time showing a tendency to split into a number of secondary channels, some of which connect it on the north with the great Ajingo Lake, and on the south with the still larger Jonanga Lake. The northmost branch of the delta—the Nazareth river, which falls into Nazareth Bay to the north of Cape Lopez—has in the driest period of the year a depth of from 20 to 30 feet, and its water is drinkable even at flood-tide. The southern arms discharge into the extensive Cama or Nkomi Lagoon and the Rio Fernão Vaz. With the exception of the Ngunie, which has been ascended 40 miles as far as the Samba falls, the affluents of the Ogoway—the Passa, Lolo, Shebe, Ivindo, Ofue, &c.—are but very partially known; and some of those from the north may prove to have a longer course than is at present supposed. The Ogoway rises in March and April, and again in October and November; it is navigable for steamers in its low-water condition as far as the junction of the Ngunie.

Though Bowditch called attention in 1817 to the existence of the river, it was not till 1857-59 that its exploration was begun by Du Chaillu. It has since been made known by the labours of Serval and Griffon du Bellay, R. B. N. Walker, Aymés, the marquis de Compiègne, A. Marche, Oskar Lenz, and Savorgnan de Brazza. English and German factories were founded about 1868 at Adelina Longa (Adaûlinaûlonga), and at Franceville, a station of the International African Association, in 1880.

See Petermann's *Mittheil.*, 1872, pp. 5-10; 1875, pp. 121-130; 1879, pp. 103-108; and 1883, pp. 177-184, with map: *Proc. R. G. Soc.*, 1873 (Walker's narrative); *Bull. de la Soc. de Géogr.*, Paris, 1877: *Zeitsch. der Ges. f. Erdk.*, Berlin, 1875 and 1876 (the former Lenz's narrative, the latter a résumé of the course of discovery by Czerny).

OGYGES, in the legends of Attica and Bœotia, was an early king in whose reign a great flood had overwhelmed the land. A similar legend was current in Phrygia, where the flood was said to have taken place in the reign of Nannacus. No facts are known connecting Ogyges with any religious cultus in Greece, and it is highly probable that the tale was of Oriental origin, introduced into this district of Greece by foreign colonists or traders. The Gephyræi, who emigrated from Bœotia into Attica, and who are said by Herodotus to have been of Phœnician origin, may have brought the story of the flood with them.

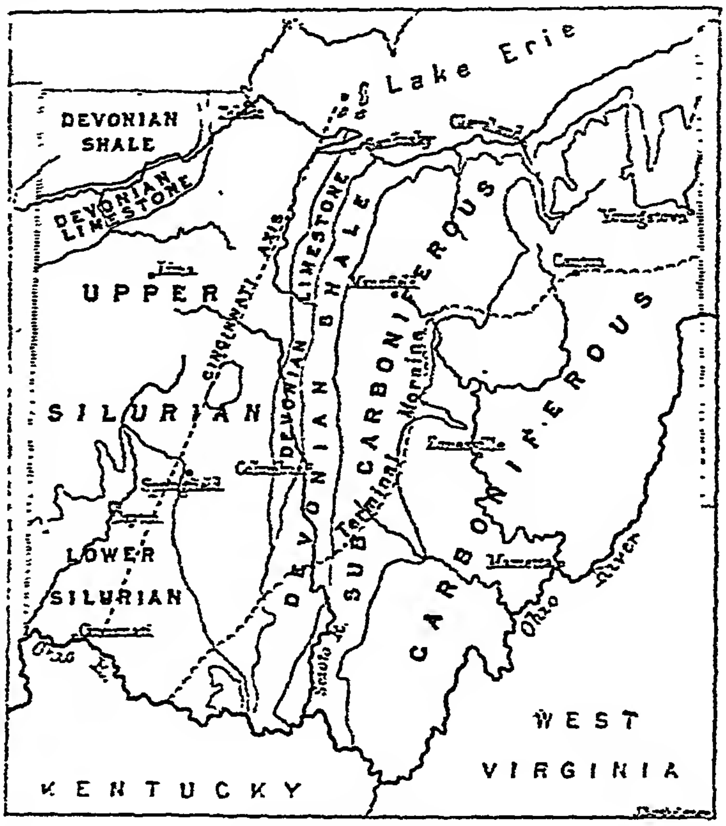
In the *peribolos* of Zeus on the banks of the Ilyssus at Athens a hole was shown through which the waters of the flood had run off, and where religious rites were regularly performed, but this hole was associated rather with Deucalion than with Ogyges.

OHIO, the third of the States of the American Union in point of wealth and population, is situated between 38° 27' and 41° 57' N. lat. and between 80° 34' and 84° 49' W. long., and is bounded on the N. by Michigan and Lake Erie, on the E. by Pennsylvania, on the E. and S. by the Ohio river, which separates it from the States of West Virginia and Kentucky, and on the W. by Indiana. The greatest length from north to south is about 210 miles, the greatest breadth from east to west about 225 miles and the area 40,760 square miles.

Physical Features.—The surface consists of an undulating plain, generally ranging in elevation between 1550 and 430 feet above sea-level, the portions below 500 feet or above 1400 being comparatively insignificant. The largest connected areas of high land extend from east to west across the central and northern central districts. In some limited districts of central Ohio, especially along the ridge of high land just referred to, and also in a few thousand square miles of north-western Ohio, the natural drainage is somewhat sluggish, and, while the land is covered with its original forest growth, it inclines to swampy conditions; but when the forests are removed and the waterways opened most of it becomes arable, and all of it can be made so without excessive outlay by means of open ditches.

The chief feature in the topography of Ohio is the watershed, which extends across the State from north-east to south-west, and divides its surface into two unequal slopes, the northern, which is much the smaller, sending its waters into Lake Erie and the Gulf of St Lawrence, while the drainage of the other is to the Gulf of Mexico by the Ohio river. The average height of the ridge is about 1100 feet, but it is cut by several gaps, in which the elevation is reduced to about 950 feet. The relief of the State is chiefly due to erosive agencies. The entire drainage area of such a river as, for example, the Muskingum or the Scioto, may be conceived as originally a plain, all portions of which were at approximately the same elevation above the sea. Across this area one main furrow has been drawn, deepening and widening as it advances, and a countless number of narrower and shallower valleys are tributary to it. Fragments of the old plain still remain in the isolated "hills" or tablelands that bound the valleys, and which, though often separated by intervals of miles, still answer to each other with perfect correspondence of altitude and stratification. They rise to a maximum height of 600 feet above the river-channels in the main valleys.

Geology.—The rocky floor is entirely composed of unaltered stratified rocks of Palæozoic age. Not a single trap dyke or volcanic vent intersects them, and not a trace of igneous metamorphism is shown in any portion of their extent. These strata are disposed in plains so nearly horizontal that the dip is nowhere heavy enough to be safely determined by a clinometer. Not only are sharp flexures wanting, but faults deserving the name are found in but a single corner of a single county. A few low folds, one of which is of preponderating importance, traverse the State and redeem its surface from geological monotony. The only structural irregularity is an occasional case of overlap, but even this is seldom of such a character as to interfere with the easy reading of the record. The aggregate thickness of the entire series will reach 5000 feet if the maximum of each stratum is taken into the account, but if the average measurements are used the thickness does not exceed 3500 feet. The main elements of the scale, which extends from the Lower Silurian (upper portion) to the Upper Coal-measures inclusive, are given below, and



Geological Map of Ohio.

the geological sketch-map shows how the surface of the State is distributed among the principal formations.

	Feet.	
Glacial Drift	0—300	
Upper barren measures	300	Carboniferous.
Upper productive Coal-measures	200	
Lower barren measures	500	
Lower productive Coal-measures (including Conglomerate group of Penna)	500	
Maxville Limestone	25	Subcarboniferous.
Waverly group	500	
Ohio Black Shale (including Cleveland, Erie, and Huron Shales) (Maximum 1500)	300	Devonian.
Hamilton Shales	25	
Corniferous Limestone	75	
Lower Helderberg Limestone	50	
Niagara Limestone	150	Upper Silurian.
Niagara Shale	50	
Clinton Limestone	25	
Cincinnati group	800	Lower Silurian.

The *Cincinnati* group, which constitutes the surface rock for about 4000 square miles in the south-western corner of the State, consists of alternating layers of blue limestone and calcareous shale, both of which contain great numbers of admirably-preserved fossils. The group is undoubtedly equivalent in part to the Hudson River group of the general scale, and by some geologists the name is counted a synonym, but it has not been proved that the Lower Silurian deposits of south-western Ohio can be definitely correlated with the subdivisions of the series in New York. The formation everywhere yields a cheap and excellent supply of building stone, which is also burned into a dark lime, valued for its hydraulic properties. The shales contain notable quantities of alkalis and phosphates, and the soils into which they very readily weather are proverbial for their fertility. The water-supply of the formation is poor, or rather wanting, the impervious shales refusing admission to the rainfall.

The Cincinnati axis, a low fold which traverses the State from south-west to north-east, constitutes its most influential geological feature. It entered Ohio from Kentucky at the close of Lower Silurian time, and gradually extended itself to the northward, until it had converted the western half of the State into dry land. It has left a clear record of its successive stages in the strata which compose it. It did not advance steadily and equally, and the occasional relapses which it experienced have given rise to cases of overlap. It has a low, flat summit, and, on account of the soluble and easily-eroded materials of which it consists, it has suffered more from denuding agencies than the Upper Silurian strata that enclose

it, and consequently is now cut down to a lower level than they. In other words, the axis has been converted into a basin.

The *Clinton Limestone* generally rises in a terrace-like outcrop around the margin of the eroded Cincinnati beds, and its base is marked by the finest line of springs in the State. In its most characteristic phases it is a crystalline limestone that takes a good polish. In very many localities it yields small quantities of petroleum, which seems to be indigenous. The supply is too limited to be valuable.

The *Niagara* group, also of Upper Silurian age, is of much greater thickness and of proportionally greater economic and scientific importance than the Clinton limestone. As at the Falls, it here consists of a stratum of shale overlain by a massive limestone. It forms the surface rock for about 3000 square miles, but through much of this area it is concealed by heavy beds of Glacial Drift, by which its importance as a factor in the topography and the economic geology of the district is much reduced. In composition the limestone is almost a typical dolomite, but it is still fossiliferous, the fossils occurring as internal casts. It contains a large and interesting fauna. From near the base of the Niagara beds the "Dayton" stone, one of the most valuable building stones of the State, is derived. The formation yields excellent building stones at other horizons also, and its upper beds furnish lime.

The *Lower Helderberg Limestone* occupies even a wider area as a surface formation than the last-named, but is largely covered with Drift deposits. There are whole counties of which it is known to constitute the rocky floor, in which it does not once rise to the surface. It is seen to the best advantage in the north of Highland county, where it yields a remarkably even-bedded building stone. Like the Niagara Limestone, it is a dolomite in composition. It is poor in fossils, but the few that it contains are highly characteristic.

The transition from Upper Silurian to Devonian time which is made in ascending to the next stratum in the scale, the *Corniferous Limestone*, is accomplished without any structural break or irregularity, but there is an abrupt lithological change, the latter stratum being a true carbonate of lime, and an abundant and pronounced Devonian fauna appears in its very lowest beds. The Corniferous Limestone forms a narrow belt on each side of the axis, from central Ohio northward, but by the overlap of the next succeeding formations it is entirely lost in southern Ohio. Even where it constitutes the highest bedded rock it is largely obscured by Drift deposits. At Kelly's Island, Sandusky, Marion, Delaware, and Columbus it is largely worked for building stone, lime, and furnace flux. The earliest vertebrate remains of the Ohio scale are found in this stratum. The box-like skull of a large ganoid fish, *Macropetalichthys sullivanti*, Newberry, occurs near the base of the series, and the teeth and bones of other ganoids and selachians are frequently met with in the higher beds. In the State quarries at Columbus these remains constitute a veritable bone bed, a layer 4 to 6 inches in thickness being in large part composed of them.

A heavy deposit of black shale, the *Ohio Shale* of the table, and the Huron shale of Newberry, directly overlies the Corniferous Limestone in northern and central Ohio, and extends across the State from north to south. It is composed of two black shales, the Cleveland and the Huron, including a blue shale, the Erie, between them. The latter is 1200 feet thick in north-eastern Ohio, but rapidly wedges out as it is followed westward to the axis, and the Cleveland and Huron seem here to be welded into one mass. The black shale contains an average of 8 or 10 per cent. of bituminous matter, a chief source of which is found in a resinous disk of microscopic size that exists in the shale in immense numbers, which Dawson has named *Sporangites huronensis*. Apart from this minute form the shale is almost barren of fossils, but a few have been discovered in it, mostly at the centres of the great concretions which it contains. The gigantic placoderm, *Dinichthys herzeri*, Newberry, was first found in these concretions. Though dating back almost to the first appearance of fishes, Newberry has shown that its nearest relationship is with the *Lepidosiren* of the present day, which zoologists unite in counting as the highest of the entire class. The shale is undoubtedly the source of the natural gas and petroleum of north-eastern Ohio.

The *Waverly* group, which occupies about 7000 square miles of the surface of the State, is in all respects an important formation. It consists of the Bedford shale, the Berea grit, the Berea shale, the Cuyahoga shale, and the Logan group. The Berea grit has unusual geological interest. Its outcrop is a shore-line across the entire State, and it marks with perfect distinctness the eastern limit of the Cincinnati axis at this date. It is everywhere a quarry stone. The Berea stone and the Amherst stone of northern Ohio and the original Waverly stone of the lower Scioto valley belong to this horizon. In strength, durability, beauty, and the economy with which they can be worked, they stand at the head of the building stones of the State, the value of the annual products of these quarries exceeding $1,000,000. The stone is distributed as far east as the seaboard, and as far west as Duluth. Some of it has even found market in England. The Berea grit is the reservoir of the gas and oil distilled from the underlying shales, and it is also the great source of salt water for Ohio. Another building stone of great excellence and beauty comes from the base of the Cuyahoga shale in southern Ohio,—the Buena Vista stone of the Ohio valley.[1]

The *Carboniferous Conglomerate* and the *Coal-measures* have an aggregate thickness of at least 1500 feet, and cover more than 10,000 square miles of the surface of Ohio. The beds of coal, iron-ore, fire-clay, limestone, and cement rock that they contain render insignificant the contributions made by all other formations to the mineral wealth of the State. The Lower Coal-measures, which are here made to include the Conglomerate group of coals of Pennsylvania, contain the seams of coal enumerated below, which are distributed through 500 to 800 feet of strata. The names of the seams that are used in the Pennsylvania scale are adopted here.

13. Upper Freeport coal	....	11	6. Brookville coal	....	6
12. Lower Freeport "	....	10	5 Tionesta "	....	5
11. (Upper Kittanning) "	......		4. Upper Mercer "	....	4
10. Middle Kittanning "	......	9	3. Lower Mercer "	....	3
9. Lower Kittanning "	......	8	2. Quakertown "	....	2
8. Clarion Upper " } 7. Clarion Lower " }	....	7	1. Sharon coal "	....	1

All these coals belong to the bituminous division. Thus far they are almost entirely worked in level free mines, and very little is taken from seams less than 3 feet in general thickness. The average thickness in the important fields is 5 feet, and the maximum (a small area of a single district) 13 feet. All of the seams enumerated above are worked, but they have very unequal values. The Middle Kittanning seam is by far the first. The Upper Freeport ranks next in value. The Sharon coal is the most valuable in proportion to its area, furnishing, in fact, the standard of comparison for the open-burning coals of the entire Alleghany field. Both it and the Middle Kittanning seam are used in the raw state in the manufacture of iron, a fact which sufficiently attests their purity and general excellence. In the remaining divisions of the Coal-measures there are 10 or 12 additional seams that are of workable thickness at some of the localities in which they occur, but, with one notable exception, these seams are less steady and reliable than those of the lower measures. The exception is the Pittsburg coal, which is, all things considered, the most important seam of the entire coal-field to which it belongs. It is especially valued as a gas coal, and for the production of steam. Its northern outcrop passes through nine counties, with an approximate length of 175 miles, not counting the sinuosities. The area commonly assigned to it in Ohio exceeds 3000 square miles, but the seam has been proved for only a small fraction of the area claimed. In the production of bituminous coal in the United States Ohio ranked third in 1880, the output for that year being about 6,000,000 tons, but the production is rapidly increasing, and the State inspector of mines reckoned the output in 1882 at 8,000,000 tons.

Iron ore is worked at many horizons in the Coal-measures, in seams ranging from 6 inches to 19 feet in thickness. The charcoal iron of the Hanging Rock district of southern Ohio is chiefly applied to the highest uses, as the manufacture of car-wheels and castings for agricultural and other machinery. Of the 99 furnace-stacks that now stand in Ohio, almost all depend in part, and about half depend entirely, on native ore. The amount mined annually exceeds 500,000 tons. In iron and steel industries Ohio ranks next to Pennsylvania, the value of the annual product being $35,000,000. The clays of the Coal-measures are the basis of a large and rapidly growing manufacture of stone and earthen ware. Ohio now produces one-third of the total product of the United States. In connexion with the salt production, which is large, about half of the bromine of the world is produced in Ohio. The brine of the Tuscarawas valley yields nearly 1 lb of bromine to 1 barrel of salt.

Three-fourths of Ohio are covered with the various deposits of the *Drift period*, which consists of "till" or boulder clay, and of the stratified sands and clays of the later stages of the period. These deposits sometimes have a thickness of 300 feet,—their average in north-western Ohio being not less than 50, and in central Ohio not less than 25 feet. In the regions which they cover they exercise a controlling influence upon the relief, drainage, soils, and water-supply. They have filled the valleys of earlier drainage systems, and in many cases have obliterated all traces of their existence. The till is filled with boulders of northern origin derived from the highlands of Canada and from intervening districts. Blocks of large size are sometimes found, some of them showing 2000 cubic feet above ground. In many instances they can be referred by their mineralogical characters to particular localities, or even to particular ledges, from a score of miles to 400 miles distant. The stratified Drift contains vast accumulations of sand, gravel, and clay, all of great economic value. Brick clays of good quality are everywhere accessible. The terminal moraine that forms the boundary of the

[1] In the total value of quarry products Ohio ranks first among the States, more than $2,500,000 being reported in the census of 1880.

Glacial deposits is not in all cases as conspicuous as in the States to the east of Ohio, but even where it is least distinct soil and vegetation unite to mark the limit of glacial advance very plainly. The moraine passes through the counties of Columbiana, Stark, Wayne, Richland, Holmes, Licking, Fairfield, Ross, Highland, Adams, and Brown, as recently determined by Professor G. F. Wright.

Soils, Forests.—The division of the State into a drift-covered and driftless region coincides with the most important division of the soils. Below the line of the terminal moraine these are "native," or, in other words, they are derived from the rocks that underlie them, or that rise above them in the boundaries of the valleys and uplands. They consequently share the varying constitution of these rocks, and are characterized by considerable inequality and by abrupt changes. All are fairly productive, and some, especially those derived from the abundant and easily-soluble limestones of the Upper Coal-measures, are not surpassed in fertility by any soils of the State. Large tracts of these excellent native soils are found in Belmont, Monroe, Noble, and Morgan counties. Among the thinner and less productive soils, which occupy but a small area, are those derived from the Devonian shales. They are, however, well adapted to forest and fruit production. The chestnut and the chestnut oak, both valuable timber trees, are partial to them, and vineyards and orchards thrive remarkably. The native soils of the Waverly group and of the Lower Coal-measures agree in general characters. They are especially adapted to forest growth, reaching the highest standard in quality of timber product. When these lands are brought under the exhaustive tillage that has mainly prevailed in Ohio thus far, they do not hold out well, but the farmer who raises cattle and sheep, keeps to a rotation between grass and small grains, and does not neglect fruit can do well upon them. The cheap lands of Ohio are found in this belt. The other great division of the soils of Ohio—viz., the Drift soils—are by far the most important, alike from their greater area and their intrinsic excellence. Formed by the commingling of the Glacial waste of all the formations to the north of them, over which the ice has passed, they always possess considerable variety of composition, but still in many cases they are strongly coloured by the formation underneath them. When any stratum of uniform composition has a broad outcrop across the line of Glacial advance, the Drift beds that cover its southern portions will be found to have been derived in large part from the formation itself, and will thus resemble native or sedentary soils. Western Ohio is underlain with Silurian limestones, and the Drift is consequently limestone Drift. The soil is so thoroughly that of limestone land that tobacco, a crop which rarely leaves native limestone soils, is grown successfully in several counties of western Ohio, 100 miles or more north of the terminal moraine. The native forests of the Drift regions were, without exception, hard-wood forests, the leading species being oaks, maples, hickories, the walnut, beech, and elm. The walnut, sugar maple, and white hickory are limited to warm, well-drained limestone land; the white oak characterizes the upland clays, while the red maple, the elm, and several of the oaks stand for the regions of sluggish drainage. This noble growth is rapidly disappearing, but several million acres still remain.

Climate.—There is a difference of at least 40° Fahr. between the average summer and winter temperatures. A central east-and-west belt of the State is bounded by the annual isotherms of 51° and 52°, the average winter temperature being 30° and the average summer temperature 73°. Southern Ohio has a mean annual temperature of 54°, and northern Ohio 49°. The annual range is not less than 100°, and sometimes 130°, the extreme of summer heat reaching 100° in the shade, while "cold waves" in winter may depress the mercury to 30° below zero. Extreme changes are liable to occur in the course of a few hours, especially in winter, when the return trades are violently displaced by north-west winds. In such cases the temperature sometimes falls 60° Fahr. in twenty-four hours; changes of 20° or 30° in a day are not unusual. Still the climate proves itself excellently adapted to the finer growths of vegetation, while its effects on human life and on the domestic animals favour a symmetrical development and a high degree of vigour. The rainfall varies between an average of 46 inches in the Ohio valley and an average of 32 inches on the shore of Lake Erie (spring 10 to 12 inches, summer 10 to 14 inches, autumn 8 to 10 inches, winter 7 to 10 inches). The annual range is considerable. In some years there is an insufficient supply and in some there is a troublesome excess, but disastrous droughts on the large scale are unknown, and disastrous floods are rare.[1] The vast body of water in Lake Erie favourably modifies the climate of the northern margin of the State. The belt immediately adjoining is famous for the fruits that it produces. Extensive vineyards and orchards have been planted along the shore and on the islands adjacent, and have proved very successful. The Catawba wine here grown ranks first among the native wines of eastern North America. Melons of excellent quality are raised in almost every section of the State. The peach is the least certain of all the fruits that are largely cultivated; there is rarely, however, a complete failure on the uplands of southern Ohio. The winters of Ohio are very variable. Snow seldom remains for thirty days at a time over the State at large, but an ice crop rarely fails in northern Ohio, and not oftener than once in three or four years in other portions of the State. In the southern counties cattle, sheep, and horses often thrive on pasture grounds through the entire winter.

Population.—The following table gives the population from 1840 to 1880:—

	Population.			Density per sq mile.
	Total.	Males.	Females.	
1840	1,519,467	784,100	735,367	37·3
1850	1,980,329	1,016,808	963,521	48·6
1860	2,339,511	1,190,162	1,149,349	57·4
1870	2,665,260	1,337,550	1,327,710	65·3
1880	3,198,062	1,613,936	1,584,126	78·5

In 1880 the coloured population numbered 2½ per cent. of the whole, and the foreign-born 12½ per cent. (from Germany 6 per cent., and from the United Kingdom 4½ per cent.).

Agriculture.—This is the leading industry, employing in 1880 397,495 persons, or about two-fifths of the total number reported as engaged in occupations of all sorts. In 1881 nearly 50,000,000 bushels of wheat and nearly 112,000,000 bushels of Indian corn were produced, the total production of cereals in the State for that year being 188,933,067 bushels, an average of sixty bushels to each inhabitant. The reported orchard products of the year would furnish ten bushels of fruit to each inhabitant, and the dairy products an average of 26 lb. The domestic animals reach a total of 10,000,000. In number and quality of thorough-bred cattle Ohio is scarcely second to any State; in the average of its herds it ranks second to

[1] Quite recently, however, the Ohio river has twice attained a height unprecedented in its former recorded history. In February 1883 the water rose to a height of 66 feet 4 inches, and in February 1884 to 71 feet 0¾ inch above the channel bar at Cincinnati, the last rise being nearly 7 feet in excess of the highest mark recorded previous to 1883. These great floods covered the sites of large and prosperous towns, swept away hundreds of dwellings, and inflicted deplorable losses on the residents in the great valley.

Illinois alone. The sheep-growing counties are supplied with the best breeds of sheep, and the wool of south-eastern Ohio has long been famous for unusual strength of fibre. The annual production of wool exceeds 20,000,000 lb, Ohio holding the first rank in this respect among the States of the Union. In the origination of agricultural machinery Ohio has taken a leading part, and in the present manufacture it easily holds the first rank, the value of the annual product exceeding $15,500,000, or one-fourth of the entire product of the United States. The average yield of wheat in the State has been doubled within the last ten years through the use of artificial fertilizers and improved methods of cultivation. An efficient system of crop reports is carried on by a State board of agriculture, and thorough control of the artificial manures sold in the State is maintained by constantly repeated chemical analyses. A State meteorological bureau also renders special service to the agricultural interest.

Manufactures, Towns and Cities.—The manufactured products of the State, according to the census of 1880, have more than twice the value of the farm products, reaching an aggregate of nearly $350,000,000. As a necessary result of the recent development of mining and manufacturing in Ohio, its cities and villages are gaining rapidly in population and wealth. Cincinnati, the largest city of the State and the eighth in the Union, had a population of 255,139 by the census of 1880. The same census credits it with about 30 per cent. of the manufactures of the State, but the reports of its chamber of commerce give it a much greater total than the census tables. Cleveland, the second city of Ohio and the eleventh of the United States, had 160,146 inhabitants, Columbus, the State capital, 51,647, and Toledo 50,137. Dayton (38,678) and Springfield (20,730) in south-western Ohio, Youngstown (15,435), Akron (16,512), and Canton (12,258) in the north-eastern quarter of the State, and Zanesville (18,113) in the central district are all thriving and energetic cities.

Government and Administration.—All legislative power is vested in a general assembly consisting of a senate and house of representa- tives. Senators and representatives are elected biennially. The executive department consists of a governor, a lieutenant-governor, a secretary of state, a treasurer, and an attorney-general, all elected for a term of two years, with an auditor, elected for four years. The supreme executive power is vested in the governor, who is com- mander-in-chief of the militia, and may grant reprieves and pardons. The lieutenant-governor is president of the senate. There is also elected triennially a State commissioner of common schools. For the control and superintendence of all public works a board of public works is created, consisting of three members, each elected for three years. There are appointed by the governor, by and with the consent of the senate, a commissioner of railroads and telegraphs for two years, a superintendent of insurance for three years, an inspector of mines for four years, a commissioner of statistics of labour for two years; also a supervisor of public printing, a State librarian, an inspector of leaf tobacco, and a State inspector of oils for two years each, and three commissioners of fisheries for three years each. To investigate the whole system of public charities and the correctional and penal institutions of the State, eight per- sons, four from each of the leading political parties, are appointed by the governor for four years each to constitute a board of State charities. The judicial power is vested in a supreme court, district courts, common pleas courts, probate courts, and justices of the peace; and the legislature may create courts inferior to the supreme court in one or more counties. The supreme court consists of five judges, elected for five years each. There are nine common pleas districts with three judges each, holding office for five years; each district is divided into three parts, with one judge (and more if the legisla- ture so provide) for each part. The district court is composed of the judges of the common pleas district together with one of the supreme court judges, any three forming a quorum. The original jurisdiction of the district court is concurrent with that of the supreme court; each county has a probate court for probate and testamentary matters. Townships are supplied with justices of the peace. All judges and justices are elected by the people. Clerks of the courts are elected by the people also. The State is divided into two United States districts, a northern and a southern. Each district is divided into an eastern and western division. All elections are by ballot, and every sane male citizen, twenty-one years old and a resident of the State for one year next preceding election, may vote. Education is provided for by taxation and funds arising from the sale of public lands. The insane, blind, and deaf and dumb are supported by the State. A sinking fund, sufficient for discharging annually the interest of the public debt and not less than $100,000 of the principal thereof, is provided from the proceeds of the public works, sale of canal, school, and ministerial lands, and taxation. The State at present is represented in the Congress of the United States by two senators and twenty-one representatives. The legislature of the State is empowered to lay off new or change existing counties. The electors in each county elect three commissioners, for three years each, who constitute the county board. They have the care of the county property, fix the taxes, regulate roads, and provide for idiots, lunatics, and paupers. The other officers are three infirmary directors, an auditor, a secretary of the commissioners, a recorder, a surveyor, a clerk of the court of common pleas, who is also clerk of the district court, each elected for three years; also a treasurer, a sheriff, a coroner, and a prosecuting attorney, each elected for two years. In a county that has in it a city of over 180,000 population there is a board of control, consisting of five members, each elected for three years, which has a final action and jurisdiction in all matters involving expenditure of money. Each county must contain at least 400 square miles of territory. Counties are subdivided into townships, the power to do which resides in the county commissioners. Each township must contain at least 22 square miles, and be at least one election precinct. The officers are three trustees, a clerk, a treasurer, such constables as the trustees may designate, and an assessor, elected annually. The trustees oversee elections, provide for the repairing of roads, make regulations preventing the spread of diseases, provide for cemeteries and libraries if the voters determine to have them, and afford relief to the poor.

Education.—The Continental Congress in 1785, in an ordinance for the survey of the lands north-west of the Ohio, reserved lot number 16 in every township, equivalent to one-thirty-sixth of the township, for the support of public schools. These provisions did not apply to the Virginia military and Connecticut reserves, equal in area to about one-fourth of the entire State, nor to the United States military reservation, embracing nearly 4000 square miles. The convention that framed the State constitution in 1802 requested and obtained of Congress a concession of one-thirty-sixth of the lands in the Virginia and United States military reservations, and a like proportion for education in the Connecticut reserve,—a portion of the latter, however, being set apart in the United States military reservation, the remainder from the public lands in the north-western part of the State (1834). Prior to 1827 the only revenues obtained from such lands were of the nature of rents, and were wholly inadequate. In the year named a law was passed providing for the sale of the school lands, other laws also being enacted for the establishment of a fund for the support of common schools. The result of the sales is somewhat disappointing, since the entire proceeds realized up to 15th November 1882 amount to but $3,686,511·56. This is known as the common school irreducible fund. The State early undertook to supplement the revenue thus acquired by a general tax; the present law provides for a tax of one mill on the dollar. Opportunity for special levies was given as early as 1821 to district officers. At present the law authorizes every board of education to determine the amount of tax to be levied as a contingent fund for all school expenses, not exceeding seven mills on the dollar. As early as 1827 the legislature adopted the policy of making offenders against the laws contribute to the support of the schools by appropriating fines collected to the school funds. This policy still continues. The receipts for school purposes in 1882 exceed $12,000,000:—

State tax (1 mill)	$1,582,263·51
Interest on irreducible fund, 1881	223,692·71
From rents and interest due for sale of lands	20,759·23
Balance on hand, 1881	3,472,577·04
From interest and rent of lands, 1882	250,431·94
Local taxes, 1882	6,168,036·89
Sale of bonds, 1882	510,646·81

Of 1,081,321 young persons of school age 751,101 are enrolled and 483,232 are in daily attendance. The school sessions average 31 weeks in the year, and 24,135 teachers are employed; the illiterates above ten years of age form only 4 per cent. of the total population. The total expenses for the common schools in 1882 were $8,820,914·95.

Higher education was not neglected by the first settlers of the State. In the Ohio Company's purchase two entire townships were granted, upon which the Ohio university was established. In the Symmes's purchase a township of land was granted, which when located served as the foundation for the Miami university. There are now 62 such institutions for learning in the State, employing 457 teachers, having 11,314 students, receiving $411,309 and expending $405,573, with a property valued at $6,203,691.

Of these, 25 are enabled by their charters to confer collegiate degrees. Among the oldest and most prominent of the colleges are Antioch, Denison, Kenyon, Marietta, Oberlin, Ohio Wesleyan, Otterbein, St Xavier's, Western Reserve, and Wittenberg; of those more recently founded three deserve special mention, viz., the university of Cincinnati, the Case School of Applied Science at Cleveland, and the Ohio State university at Columbus. The first two are founded upon private munificence, and each is entering upon a career of great promise. The third, established upon a gift of public lands from the general Government, is specially charged with instruction in the sciences relating to agriculture and the mechanic arts, and is also required to include military training. In addition, therefore, to the ordinary courses of an American college, this institution is obliged to provide full facilities in applied science, and the State makes use of its faculty and equipment for all its official scientific work. The chemical work of the State Board of Agriculture and also of the State Geological Survey is performed here. The Agricultural Experiment Station and the State Meteorological Bureau are both at the university.

Finance.—The receipts of the Ohio treasury for 1882 were \$6,270,396·22, and the disbursements \$5,630,219·29. The funded State debt at 15th November 1882 was \$4,901,665, all at 4 per cent., and the irreducible debt (trust) was \$4,393,014·71, making a total State debt of \$9,294,679·71, while the municipal and local debts amount to \$45,766,351·22, making a total public debt of \$55,061,030·93. The value of the realty was \$1,116,681,655, and personalty \$518,229,079, or a total valuation of \$1,634,910,734. The State tax paid was \$4,735,748, while the total tax was \$30,618,785. Banks numbered 413, with a capital stock of \$38,152,855·30; 189 were national, with a stock of \$31,464,000, valued at \$1,133,792·40. There were 6189 miles of railway,—receipts \$46,759,399, expenditure \$32,063,654.

History.—Ohio was discovered by La Salle, probably as early as 1670, and the French took formal possession of the whole north-west in 1671. In 1749 all English settlers were warned by the French commandant at Detroit to retire from the region north of the Ohio. The settlements had been made under the third charter granted by King James I. to Virginia (12th March 1611), which ceded to the colony all of the present State of Ohio lying south of 41° N. lat., and that granted by Charles II. to Connecticut (23d April 1662), which ceded to the colony all the territory of the present State lying north of 41° N. lat. The conflicting claims were set at rest by the treaty of Paris in 1763, by which France surrendered to Great Britain all her lands in the north and west as far as the Mississippi. During the progress of the American Revolution, and while the States were struggling to form a union on the basis of the articles of confederation submitted for ratification in 1777, a controversy arose as to the rightful ownership of unoccupied lands. The States appealed to their charters, as did Virginia and Connecticut, for their title to the lands north-west of the Ohio. The opposing States claimed that the unoccupied lands, though charter lands, should be surrendered for the common benefit, to become the property of the new union. The controversy was settled in some cases, as in that of New York, by the abandonment of all claims by the State; in others, among them Virginia and Connecticut, compromises were entered into by which the States made large reservations in the acts of surrender. Virginia reserved for military bounty lands about 3,710,000 acres, lying between the Scioto and Little Miami rivers, and bounded on the south by the Ohio river. Connecticut reserved as a foundation for her school fund a tract extending 120 miles westward of the Pennsylvania line, bounded on the south by 41° N. lat., and by the Connecticut line on the north. The land area extended to about 3,667,000 acres. In 1800 Connecticut surrendered all jurisdictional right over these lands to the United States.

Among the last and most important acts of the Congress of the old confederation was its passing the ordinance of 1787, providing a government for the territory north-west of the Ohio. The ordinance is a remarkable document in many particulars, and especially for the clause in its sixth article, which reads: "There shall be neither slavery nor involuntary servitude in said territory, otherwise than in the punishment of crimes, whereof the party shall have been duly convicted,"—a clause which, after appearing in many State documents, at last became the property of the nation when it was adopted as the thirteenth amendment of the constitution of the United States. The passing of the ordinance was closely connected with the purchase of a million and a half of acres upon the Ohio, and in the Muskingum valley, by the Ohio Company. On 9th July 1788 General St Clair, the governor, and his associates, Judges Parsons, Varnum, and Symmes, formally established the government of the Territory at Marietta, the newly-formed settlement of the company, situated on the Ohio at the mouth of the Muskingum, and named after Marie Antoinette. The next considerable purchase of land was made by Judge Symmes, who secured upwards of 311,000 acres on the Ohio, between the Great and Little Miami rivers. The site of Cincinnati was purchased from Judge Symmes by Mathias Denman of New Jersey, whose surveys marked out in the winter of 1788-89 the town that has since grown to be the leading city of the State. Two expeditions sent against hostile Indians at the head-waters of the Miamis in 1790 and 1791 resulted in such disastrous failure that the settlers began to despair of protection. However, in 1794 General Wayne won a decisive victory over the united tribes near the rapids of the Maumee, and at the treaty of Greenville, contracted a year later with eleven chiefs, secured peace. As a result, the rapid immigration which followed enabled the residents of the Territory to avail themselves of the provisions of the ordinance in organizing a representative government for the Territory by electing a legislature, which held its first session in Cincinnati 24th September 1799. By authority of Congress a convention which met at Chillicothe in November 1802 drafted and on the 29th day of the month signed and ratified for the people the first constitution of Ohio. Several stipulations relative to school lands were made by the convention in the constitution submitted to Congress, which were conceded, and the State was admitted 19th February 1803 as the fourth under the constitution of the United States, and the seventeenth in the roll of the States. Chillicothe, which in 1800 had been made the seat of government for the North-West Territory, continued to be the capital of the State until 1810, when the Government removed to Zanesville for two years. Returning to Chillicothe, it chose Columbus in 1816 as the permanent capital of the State.

In 1821 a movement for internal improvements was inaugurated, which culminated in the construction of a canal from the Ohio to Lake Erie through the valleys of the Scioto and the Muskingum, and another from Cincinnati to Dayton. Fortunately the movement for common schools began at the same period. The canals set free the locked-up produce of the interior, and the State entered upon a new life. The completion of the Cumberland road in 1825, as far as Wheeling on the Ohio, gave the State an outlet to the seaboard. While the canals were yet incomplete the construction of railroads was undertaken. The Mad River and Lake Erie Railroad from Dayton to Sandusky was the first, being chartered in 1832 and actively begun in 1835. In 1852 three through lines had been opened across the State; and its whole social and economic history thenceforward assumed a new character. Since 1840 Ohio has been the third State in the Union in point of population.

The present constitution of the State is the result of a revision of that of 1802 by a convention which assembled in Columbus 6th May 1850, and sat during part of its session at Cincinnati. It completed its work 10th March 1851, and the people ratified the revised constitution 17th June 1851. A second convention of revision was assembled in Columbus 14th May 1873, which, like its predecessor, sat also in Cincinnati. The constitution submitted, practically a new one, was rejected by the people at the October election of 1874. (E. O.—J. T. S.)

OHIO RIVER. See Mississippi, vol. xvi. p. 518.

OHM, Georg Simon (1781-1854), was born at Erlangen in 1781 and educated at the university there. He became professor of mathematics in the Jesuits' college at Cologne in 1817 and in the polytechnic school of Nuremberg in 1833, and in 1852 professor of experimental physics in the university of Munich. He died 6th July 1854.

His writings are numerous, but, with one important exception, not of the first order. The exception is his pamphlet published in Berlin in 1827, with the title *Die galvanische Kette mathematisch bearbeitet.* This work, the germs of which had appeared during the two preceding years in the journals of Schweigger and Poggendorff, has exerted most important influence on the whole development of the theory and applications of current electricity. Nowadays "Ohm's Law," as it is called, in which all that is most valuable in the pamphlet is summarized, is as universally known as anything in physics. It may be doubted whether Ohm's investigation could have been made but for the magnificent work of Fourier on the *Conduction of Heat.* In fact, the equation for the propagation of electricity formed on Ohm's principles is identical with that of Fourier for the propagation of heat; and if, in Fourier's solution of any problem of heat-conduction, we change the word "temperature" to "potential" and write "electric current" instead of "flux of heat," we have the solution of a corresponding problem of electric conduction. The basis of Fourier's work, without which even his splendid mathematical powers would have been of no avail, was his clear conception and definition of conductivity. But this involves an assumption, undoubtedly true for small temperature-

gradients, but still an assumption, viz., that, all else being the same, the flux of heat is strictly proportional to the gradient of temperature. An exactly similar assumption is made in the statement of Ohm's law, *i.e.*, that, other things being alike, the strength of the current is at each point proportional to the gradient of potential. It happens, however, that with our modern methods it is much more easy to test the accuracy of the assumption in the case of electricity than in that of heat; and it has accordingly been shown by Maxwell and Chrystal that Ohm's law is true, within the limits of experimental error, even when the currents are so powerful as almost to fuse the conducting wire. The value of Ohm's work was but imperfectly recognized until it was stamped by the award of the Copley medal of the Royal Society in 1841.

OIL-CAKE. The solid compressed mass remaining after the expression of oil from the many oil-yielding seeds, nuts, &c., forms a material of considerable commercial importance. It retains after the most perfect treatment by pressure no inconsiderable portion of oil, with practically the whole of the albuminous matter, sugar, mucilage, and the starchy components of the seeds, &c., thus forming in most cases a concentrated nutritious food for cattle and sheep, specially valuable for fattening store animals for the market. The only commercial cakes which are unfit for animal food are such as contain purgative or other active principles, as, for example, the cakes of castor-oil seed, croton seed, purging-nut seed, and mustard seed. The most valuable and at the same time the most abundantly produced feeding-cake is that obtained from ordinary Linseed (*q.v.*). Next in value is the cake yielded by rape seed, but its wholesomeness is frequently marred by the presence of a large proportion of acrid mustard seed; the best is that yielded by the German green rape seed (*Brassica rapa oleifera*). Cotton-seed cake is also a feeding stuff of considerable importance. It is prepared in two forms, either as decorticated cake, in which the husks of the cotton seed are removed previous to the expression of the oil, or as undecorticated cake, which may contain as much as 40 to 50 per cent. of indigestible woody husk. Among other cakes useful for feeding purposes may be enumerated ground-nut cake from *Arachis hypogæa*, palm-kernel cake from the seeds of the oil palm, sesame or til cake from the seed of *Sesamum orientale*, and hemp cake from the seed of *Cannabis sativa*. The following table indicates the average composition of a few of the principal commercial cakes.

	English Linseed Cake.	German Green Rape Cake.	Decorticated Cotton Cake.	Undecorticated Cotton Cake.	Sesame Cake.	Hemp Cake.	Palm-Kernel Cake.
Water	12·41	10 82	9·28	11·46	8 06	10 00	9·50
Oil	15·64	8·72	16·05	6·07	11 34	8·26	8 43
Albuminous bodies*	27·87	33 81	41·25	22 94	36 87	21·50	30·40
Mucilage, sugar, and digestible fibre	23·79	28·05	16·45	32 52	25·05	48·00 }	40 95
Woody fibre	14 85	11·49	8·92	20 09	8·14	..	
Mineral matter	5·44	7·10	8·05	6 02	10 54	12·24	10·72
*Containing nitrogen	4·46	5·41	6·58	3·67	5·90	3 30	4·50

Oil-cake should be thoroughly dried by exposure before being packed or stored, otherwise it is apt to heat, and turn sour and mouldy, in which condition it becomes injurious to cattle. The cake also made from rancid seed is frequently deleterious, and so disagreeable in taste as to be refused by animals. Oil-cakes of high value are subject to adulteration; and compounds of varying composition are prepared and sold under commercial brands simply as feeding cake or mixed cake with no indication of their component materials. These are usually largely intermixed with bran, husks, ground rice, and maize siftings, &c.

OIL CITY, a city of the United States, in Venango county, Pennsylvania, at the junction of Oil Creek with the Allegheny river, lies 132 miles north-north-east of Pittsburg by the Allegheny Valley Railroad, in the heart of the Venango petroleum district, and possesses the principal oil exchange of the world, the transactions in 1883 amounting to 1,129,199,500 barrels, valued at $1,209,654,064. The business part of the city is on the low ground north of the river, the residences occupying the south side and the high bluffs on the north side. Besides manufactories connected with the oil industry, the city has machine-shops, foundries, flour-mills, and breweries. Founded in 1860, and partially destroyed by flood in 1865 and by flood and fire in 1866, Oil City was incorporated as a city in 1871. Its population was 7315 in 1880, and now (1884) is estimated at 10,000.

OILS. The term oil is a generic expression under which are included several extensive series of bodies of diverse chemical character and physical properties. In its most comprehensive ordinary acceptation the word embraces the hard solid odourless waxes, tallows, and fats, the viscid fluid fixed oils, the odorous essential oils, and the solid, fluid, and volatile hydrocarbons obtained in nature or by destructive distillation. Further, in former days, when substances were principally classified by obvious physical characteristics, the word applied to various substances which, beyond an oily consistency, possess no other properties in common with ordinary oils. Thus we have still in common use for sulphuric acid the term "oil of vitriol," a substance which, it need hardly be said, is widely different from any oil. Leaving out of account bodies of this nature, the remaining diverse bodies have in common the characters that they are compounds consisting principally, in some cases exclusively, of carbon and hydrogen, that they are mostly insoluble in water, and that they are all readily inflammable. The mineral hydrocarbons obtained either in nature or by destructive distillation do not come within the range of this article (see Naphtha, Paraffin, Petroleum), which is restricted to the series of neutral bodies formed naturally within animal or vegetable organisms. These bodies are divided into two well-defined groups—the fixed oils and fats, and the essential or volatile oils.

Fixed Oils.

The fixed or fatty oils, although varying considerably in external appearance, form in reality a well-defined and homogeneous group of substances having great similarity of chemical composition. They appear to be essential constituents of the most highly-organized forms of animal and vegetable life, being found in plants chiefly in the seed, and in animals chiefly enclosed in the cellular tissue and in special body cavities, but some proportion of fatty matter is found in almost all tissues and organs. Although oils and fats are universally distributed and perform most important functions in animal and vegetable life, those used for technical purposes are not drawn from any very great number of sources; and many bodies might be utilized for the production of oil which at present are not so employed.

As found in commerce, oils possess a faint characteristic taste, a slight odour, and some amount of colour, generally brownish yellow. These characteristics, however, are due to certain impurities; in a really pure condition most oils have scarcely any characteristic taste, odour, colour, or physiological influence. In a few cases only they have special properties which appear to be inseparable characteristics, such as the purgative principle of castor oil, croton oil, and some others. At the ordinary temperatures most vegetable oils are fluid, but a few, produced especially by tropical plants, such as palm oil, cocoa butter,

Chinese tallow, &c., are solid fats. Animal fats are for the most part solid, the oils of marine animals and neat's-foot oil being important exceptions. The various solid fats differ greatly in consistency, and the hardness of individual samples is largely affected by the nature of the food and by the health of the animal yielding them, and by some other circumstances. The relative fluidity or solidity of the various oils and fats depends on the proportions of the three principal constituents of all oils—olein, stearin, and palmitin. The fluid oils contain olein in larger proportion, that body being itself liquid at ordinary temperatures, while solid stearin and palmitin predominate in the hard fats. The viscosity of the fluid oils also ranges between wide limits. The rate of flow of an oil, which is a matter of considerable importance in several industrial applications, is estimated by comparison with the standard rate at which water of the same temperature flows through an aperture of fixed dimensions. The most viscid of the fluid oils is castor oil, which at a temperature of 15° C. is more than two hundred times thicker or more slow-flowing than water. Olive oil at the same temperature is more than twenty times thicker, and linseed and hemp oils, though among the most limpid of fixed oils, still flow about ten times as slowly as water.

Oils communicate to paper and like substances a stain which remains an irremovable translucent grease spot. They are almost entirely insoluble in water, and, excepting croton and castor oils, in cold alcohol, but in boiling alcohol they dissolve more freely, and they are perfectly soluble in ether, bisulphide of carbon, chloroform, benzol, and light petroleum spirit. In their pure condition they are neutral bodies, but, on their becoming rancid, free fatty acids are developed which give them an acid reaction. Exposed to air they absorb oxygen freely, and the class containing linoleic acid, known as drying oils, of which linseed oil is the type, thereby harden into a solid translucent semi-elastic caoutchouc-like body, a property of the utmost value in the arts. When they are exposed in thin layers over a great surface the absorption of oxygen proceeds with such energy that heat is evolved sufficient to produce spontaneous combustion, a circumstance frequently exemplified in the heating and igniting of heaps of oily cotton waste. The non-drying oils also on exposure to air thicken and become greasy; they acquire the peculiar disagreeable smell and acrid taste known as rancidity, owing to a kind of fermentation being set up in them through the agency of impurities, whereby the fixed fatty acids they contain are decomposed, and odorous volatile fatty acids formed by oxidation at their expense.

The specific gravity of all oils is lower than that of water, ranging from ·900 in the case of cocoa butter to ·970, the specific gravity of castor oil. Most fluid oils have a specific gravity between ·915 and ·930. The specific gravity of oils varies with the temperature far more than is the case with water. It is found that for each degree Centigrade rise of temperature whale oil increases in volume 1 per 1000, rape oil 0·89, and olive oil 0·83.

When a solid fat is heated slowly till it melts and is allowed gradually to cool, it remains fluid till it falls considerably under the temperature at which it melted, and at the moment of solidification there is a sensible increase in its temperature. Butter, for example, melts at 30° to 31°·5 C., but does not resolidify till it falls to 19° or 20° C. These phenomena have been investigated in the case of the pure fats stearin and palmitin by Duffy (*Chem. Soc. Qu. J.*, v. 197), who finds that these bodies undergo with great readiness three isomeric modifications, each having a distinct melting point widely apart from each other (stearin from beef giving 51°, 63°, and 67°), the solidifying point being slightly under the lowest of the three. The freezing point of the ordinary fluid oils ranges down to from −27° to −28° C. for hemp oil, nut oil, and linseed oil, while olive oil solidifies at +2° to 4° C. Fluid oils heated to from 280° to 300° C., and solid fats to from 300° to 325° C., undergo destructive distillation, resolving into a mixture of rich inflammable gases and a peculiarly irritating acrid vapour, acrolein.

Oils and fats are compounds of carbon, hydrogen, and oxygen, in proportions ranging, as a rule, for carbon between 76 and 80 per cent., hydrogen from 11 to 13 per cent., and oxygen from 10 to 12 per cent. Their proximate constitution was first demonstrated by Chevreul, who indeed, in the great series of classical researches embodied in his *Recherches sur les corps gras d'origine animale* (1823), established the modern chemistry of oils.

The phenomena of saponification, as exemplified on a great scale in the important industry of soap-making, furnished the key for discovering the intimate constitution of oils. Oils and fats treated with alkalis, alkaline earths, and basic metallic oxides in presence of water undergo decomposition and enter new combinations. A soap is formed by the union of the alkaline body with acid constituents of the oil, known as fatty acids, and the sweet body, glycerin, is liberated. The saponification of stearin with sodic hydrate, for example, may be thus represented:—

$$\underset{\text{Stearin.}}{\left.\begin{matrix}(C_{18}H_{35}O)_3\\ C_3H_5'''\end{matrix}\right\}O_3} + \underset{\substack{\text{Sodic}\\ \text{hydrate.}}}{\left.\begin{matrix}3Na\\ H\end{matrix}\right\}O} = \underset{\substack{\text{Stearate of}\\ \text{sodium (soap).}}}{\left.\begin{matrix}3C_{18}H_{35}O\\ Na\end{matrix}\right\}O} + \underset{\text{Glycerin.}}{\left.\begin{matrix}C_3H_5'''\\ H_3\end{matrix}\right\}O_3}.$$

By heating oil with steam under a pressure of from 10 to 12 atmospheres, or with water superheated to about 220° C., the oil is decomposed into free fatty acid and glycerin. Thus, again taking the simple fat stearin, we have:—

$$\underset{\text{Stearin.}}{\left.\begin{matrix}(C_{18}H_{35}O)_3\\ C_3H_5'''\end{matrix}\right\}O_3} + \underset{\text{Water.}}{3H_2O} = \underset{\text{Stearic acid.}}{\left.\begin{matrix}3C_{18}H_{35}O\\ H\end{matrix}\right\}O} + \underset{\text{Glycerin.}}{\left.\begin{matrix}C_3H_5'''\\ H_3\end{matrix}\right\}O_3}.$$

In the above reactions it will be observed that three molecules of water are required for the formation of free stearic acid and glycerin from one molecule of stearin, and to that extent the resulting products are heavier than the original. Reading the equation in the inverse manner we find the formation of stearin takes place by the substitution of the three acid residues of stearic acid $C_{18}H_{35}O$ for the three hydroxyls $H.O$ in the molecule of glycerin. No fat or oil is found in nature consisting of a single chemical fat such as stearin alone. All are mixtures of at least two and for the most part three or more simple fats or glycerides of fatty acids closely allied in nature and constitution. These glycerides or combinations of glycerin and fatty acids are in their chemical relations ethers. Glycerin itself is a triatomic alcohol, and bears to the fatty acids and resulting ethers the same relation which a basic substance bears to an acid and to the salt which results from their combination. In all natural fats glycerin combines, as in stearin, by having substituted for its three replaceable hydrogen atoms three equivalents of fatty acids, whence the natural simple fats are all triacid compounds—tristearin $\left.\begin{matrix}(C_{18}H_{35}O)_3\\ C_3H_5\end{matrix}\right\}O_3$, tripalmitin $\left.\begin{matrix}(C_{16}H_{31}O)_3\\ C_3H_5\end{matrix}\right\}O_3$, triolein $\left.\begin{matrix}(C_{18}H_{33}O)_3\\ C_3H_5\end{matrix}\right\}O_3$, &c., though commonly called stearin, palmitin, and olein, &c. (For further information as to the constitution of glycerides see GLYCERIN, vol. x. p. 697.) The three simple fats above named form by far the largest and most important constituents of all oils and fats, the only others which bulk largely being the glycerides of linoleic acid in drying oils, and of physetoleic acid characteristic of marine oils. The number of fatty acids found combined with glycerin in oils is, however, very considerable. They constitute members of homologous series, the first or stearic series of which possess the common formula $C_nH_{2n}O_2$. Belonging to it are the following:—

		Boiling and Melting point.	Substances in which chiefly found.
Acetic	$C_2H_4O_2$	118° C	Butter fat.
Butyric	$C_4H_8O_2$	156° C.	Butter fat.
Caproic	$C_6H_{12}O_2$	194° C.	Cocoa-nut oil, butter fat.
Caprylic	$C_8H_{16}O_2$	232°	Cocoa-nut oil, butter fat.
Capric	$C_{10}H_{20}O_2$	Melt. pt. 39°	Cocoa-nut oil, butter fat.
Lauric	$C_{12}H_{24}O_2$	" 43°·6	Cocoa-nut oil, bayberry oil.
Myristic	$C_{14}H_{28}O_2$	" 53°·8	Oil of mace, &c.
Palmitic	$C_{16}H_{32}O_2$	" 62°	Lard, palm oil, &c.
Stearic	$C_{18}H_{36}O_2$	" 69°·2	Tallow, &c.
Arachidic	$C_{20}H_{40}O_2$	" 75°	Ground nut oil.
Behenic	$C_{22}H_{44}O_2$	" 75°	Ben oil.
Cerotic	$C_{27}H_{54}O_2$	" 78°	Beeswax.
Melissic	$C_{30}H_{60}O_2$	" 88°	Beeswax.

Another, the oleic series, contains two atoms less of hydrogen than the allied stearic series, having the general formula $C_nH_{2n-2}O_2$. To it belong the following:—

		Boiling and Melting point.	Substances in which chiefly found.
Crotonic	$C_4H_6O_2$	Boil. pt. 72°	Croton oil.
Hypogæic or Physetoleic	$C_{16}H_{30}O_2$	Melt. pt. 34°	Earth nut oil and whale oils.
Oleic	$C_{18}H_{34}O_2$	....	Most fats and fluid oils.
Brassic	$C_{22}H_{42}O_2$	,, 33°	Rape and mustard oils.

To these there remain to be added, not members of either series, two important fatty acids,—linoleic acid, $C_{16}H_{28}O_2$, characteristic of linseed oil and other drying oils, and ricinoleic acid $C_{18}H_{34}O_3$, the chief product of the saponification of castor oil. Among saponifiable bodies the true waxes are distinguished from other solid fats by containing no glycerin. They are principally ethers of the higher monatomic solid alcohols—cetylic and cerylic alcohol, &c. Thus spermaceti, the solid wax obtained from the head matter of the sperm whale, is a cetyl palmitate $\left.\begin{matrix}C_{16}H_{31}O\\C_{16}H_{33}\end{matrix}\right\}O$. Certain of the vegetable waxes—*e.g.*, Japanese wax—contain some proportion of glycerides.

Extraction of Oil.

The ordinary method for separating vegetable oils and fats from the nuts, seeds, &c., of which they form constituent parts is by pressure, with or without the assistance of heat. They are also obtained by the agency of solvents, principally by the use of bisulphide of carbon and the light petroleum spirit benzin, these being methods of production of comparatively recent introduction. Animal oils and fats are principally isolated by simple melting or "rendering" by heat. The degrees of heat and pressure necessary for separating the several fats vary very much with the fluidity of the oils themselves, the proportion in which they are present in the substances, and the nature and consistence of the associated materials. Spermaceti oil exists indeed in its fluid condition in the head itself of the sperm whale. Virgin olive oil is obtained with the gentlest pressure, and palm oil and several other vegetable fats and waxes are liberated by the agency of boiling water.

Vegetable Oil Pressing.—Pliny describes in detail the apparatus and processes used for obtaining olive oil among his Roman contemporaries, by which it appears that they derived a knowledge of the screw press from the Greeks, and applied it to the pressure of oil from pulped olives. In the East, where vegetable oil forms a most important article for food and for other personal and domestic purposes, various ingenious applications of lever presses and of combined lever and wedge presses have been in use from the earliest times. The Chinese employ the same series of operations which are followed in the most advanced oil mills of modern times, viz., bruising and reducing the seeds to meal under an edge-stone, heating the meal in an open pan, and pressing out the oil in a wedge press in which the wedges are driven home by hand hammers. The apparatus used in Europe in modern times for the extraction of oil by pressure consists of forms of the screw press, the Dutch or stamper press, and the hydraulic press. With the screw press, even of the most improved form, the amount of pressure practically obtainable is limited from the failure of its parts under the severe inelastic strain which can be put on it. It is on this account only used in the pressure of olives and of animal fats, where the power necessary is not great. The Dutch or stamper press, which has played an important part in the oil industry, was invented, as its name indicates, in Holland in the 17th century. The invention of the hydraulic press in 1795 effected the greatest revolution in the oil industry, bringing a new, easily controlled, and almost unlimited source of power into play, and on the great scale that apparatus has practically superseded all other means of pressing.

The sequence of operations in treating oil-seeds for the separation of their contained oils is ordinarily as follows:—(1) the crushing and grinding of the seed or other substance, (2) heating the oleaginous meal so prepared, and (3) expression of the oil by mechanical power.

Grinding.—As a preliminary operation oil-seeds are freed from dust, sand, and other impurities by sifting in an inclined revolving cylinder or screening machine, covered with woven wire having meshes varying according to the size and nature of the seed operated upon. In earlier times the seeds were pounded to meal by means of stamper mills. These consisted of a series of heavy wooden stampers or pestles made to rise and fall by the action of cams or wypers fixed on a revolving shaft, a pair of such stampers falling alternately with heavy force into an egg-shaped mortar about two-thirds filled with seed. As the process proceeded the material became heated, and from time to time had to be sprinkled with water. Stampers are now seen only in small old-fashioned establishments. In a modern oil-mill the screened seed is passed through crushing rollers to bruise or open the husk. The crushing rollers consist of a pair of cast-iron rollers horizontally mounted, commonly of unequal size, the larger being 4 feet in diameter, while the smaller is about 1 foot. The larger roller is revolved by power and the smaller moves by simple friction against the other. Between these rollers the seed is fed by a hopper, and in passing through it is bruised and broken and so prepared for the thorough grinding it receives under the revolving edge-stones to which it next passes. These are a pair of circular stones having a diameter of about 7 feet with a thickness at their running edge of 16 inches, each weighing from 2½ to 3½ tons. They are made of very compact limestone, granite, or fine-grained sandstone, and are mounted on a vertical driving shaft, to which they are attached by a horizontal axle passing through their centre. They revolve on a bed of similar hard compact stone, and the compound rubbing and bruising effect of their rotary motion quickly reduces the bruised seeds to a fine meal. The stones are provided with sweepers, which in their revolution bring the material pressed out towards the side again into their path, and there is a separate sweeper for clearing out the finished meal from the bed of the machine by way of a slide or door provided in the side. The edge-stones revolve about twenty times per minute, and a charge of seed which is slightly moistened during the process is sufficiently ground on an average in about twenty-five minutes.

Heating.—In dealing with certain oils which are easily separated, and especially with oils used in cookery and otherwise consumed, where it is desirable to preserve the pleasant, bland, and faint fruity or nutty taste, the ground oleaginous meal is taken direct to the press and pressed for cold-drawn or virgin oil. The cake from such cold pressing, as it still retains a large proportion of oil, is subsequently broken up, reduced to meal, and heated; after which it is again subjected to pressure to obtain a further flow of oil. Ordinarily, however, the meal is artificially heated previous to any pressure, and it depends greatly on the nature of the seed and the individual manufacturer's method of working whether the material is fully pressed at first or twice submitted to the operation. The warming of the seed meal renders the contained oil more fluid and consequently more readily separable with moderate pressure. It also enables the oil-presser to obtain a larger proportion of the contained oil, coagulates and holds back the albuminous constituents of the seeds, and similarly dries and retains mucilaginous matter. On the other hand, oil from heated meal usually is more highly coloured and harsher to the taste than cold-drawn oil; and the quality is seriously deteriorated if by chance the heat applied should exceed at most 80° C. The heat is applied either in open shallow iron kettles or pans heated over a direct fire or through a sand-bath; but preferably, and now generally, the meal is heated by steam circulating freely between the casings of a jacketed or double-walled pan or pans. Mechanical stirrers are kept in continuous rotation within the pan, to ensure a uniform warming effect throughout the mass. A highly-approved and convenient form of heating apparatus consists of a double steam kettle, one pan being placed above the other, each steam-jacketed and provided with mechanical stirrers. In this machine the heating action is continuous. The meal is first heated for ten or fifteen minutes in the upper pan, which is closed over with a sheet-iron cover, after which a slide in the bottom of the pan is opened and the charge is shot down into the lower pan, where it is raised to the full heat, while the upper pan is again recharged and worked up. When fully heated in the lower pan the charge is swept out at a door in the side of the pan by the action of the mechanical stirrers, and falling into a funnel is passed in measured quantities direct into bags, and without delay prepared for and placed in the press. The kettles are of a capacity sufficient to heat seed for charging three single presses at each operation. A form of heating kettle is also now in use in which the object is effected by direct injection of steam into the mass, whereby the meal is not only heated but a beneficial amount of moisture is distributed throughout the material. In mills of the most recent construction such steam kettles are used in connexion with an improved form of crushing rollers,—employment of edge-mills being dispensed with. These rollers consist of a series of four or five chilled iron or steel cylinders mounted in vertical order like the bowls of

a calender. The seeds pass in succession between the first and second rollers in the series, then between the second and third, and so on till they are delivered by the lowest, sufficiently bruised, crushed, and ground.

Pressing.—With the least possible delay the meal is transferred from the heating kettles, so that the oil may be pressed out while the material still retains its heat. Measured quantities, say 10 to 12 lb of meal, are filled into woollen bags of strong, thick texture, sufficiently open and porous to allow free flow of the expressed oil, yet having consistency enough to resist rupture by the enormous pressure to which it is subjected. Each bag is further placed within "hairs," thick mats of horse-hair bound with leather. In some methods of working press-cloths—not bags—are used; and the construction of recent presses is such as to dispense altogether with the use of bags or other coverings. The essentials of proper oil-pressing are a slowly accumulating pressure, so that the liberated oil may have time to flow out and escape, a pressure that increases in proportion as the resistance of the materials increases, and that maintains itself as the volume of material decreases through the escape of the oil. These essentials the Dutch or stamper press and the hydraulic press fulfil perfectly, and the prevalence of hydraulic pressure over the other and older method is only due to the greater convenience and ultimate economy of the power. Previous to the early years of the present century the Dutch press was almost exclusively employed in Europe for pressing oil-seeds. It consists of two principal parts, an oblong rectangular box with an arrangement of plates, blocks, and wedges, and over it a framework with heavy stampers, the fall of which produces the pressure. The press box is made either of cast-iron or, according to the older method, of strongly-bound oaken planks. At each extremity of the box there is placed a bag of oil-meal between two perforated iron plates, under which are a perforated bottom and channels for conducting away the expressed oil. Next are inserted filling-up pieces of wood, two of which—the spering-blocks—are oblique or bevelled on one face, forming ways for the two wedges which press against them. Between the spering-blocks, and separated also by a filling piece, are inserted the two wedges, one being the ordinary or driving wedge by which the pressure is applied to the seed-bags, and the other an inverted or spring wedge, which is only driven down to loosen and free the various parts when the pressing operation is complete. The stamper which drives home the ordinary wedge is a heavy log of wood about 16 feet long by 8 inches square, and it falls about fifteen times a minute through a maximum distance of 22 inches by the action of a pair of cams or wypers fixed on a revolving shaft. As soon as the pressure is complete the stamper suspended over the inverted wedge is brought into action, and by a single heavy blow knocking the wedge out of its key-like position it frees the various parts of the apparatus for the removal of the pressed cakes. In a double stamper press about 12 cwt. of finished cake is made per day. Since the introduction of the Bramah press, numerous modifications have been invented with the special object of improving its convenience as an oil-press. The various forms devised for oil-extracting may be comprehended under standing or vertical presses and horizontal or lying presses, with specially-modified seed-boxes and press plates in each instance. The most primitive form of upright press, and one which still recommends itself for simplicity where great pressures are not essential, is a drum or box press, so called because on the platen are placed two circular metal tubs, one within the other, the inner perforated throughout for the escape of the oil. At the top of the press is secured a strong metal plate or table the same diameter as the inner box, and the seed is pressed by the working up of the ram carrying the box against the surface of this table. Within the perforated box the seed-bags are deposited with metal plates between them. Experience, however, has demonstrated that the best presses are those provided with separate trays or seed-boxes for each bag, and the ordinary oil-press of the present day is fitted with four seed-boxes, and presses four separate cakes at one working. A convenient form is the double oil-press of Blundell, which admits of continuous working, one division being under pressure, while the other division is being emptied and recharged. The final pressure applied in ordinary practice on the seed-trays in an hydraulic press is equal to a weight of about 300 tons. This weight is allowed to remain on for seven minutes, and the whole operation of charging, pressing, and emptying a press may be finished in ten minutes. A Blundell double press is capable of working off about 5 cwt. of seed per hour. A form of press of the most recent and improved construction, called the "pack press," dispenses with bags, seed-boxes, and hair-mats. Consolidated cakes of seed enclosed in press cloths to the number of sixteen for one charge are simply piled between corrugated plates. To enable the press to be charged with sufficient rapidity, and to allow the large number of bags to occupy as small a vertical space as practicable when placed in the press, a moulding or form machine, such as was invented by [illegible] Berrie of Glasgow and patented in October 18[illegible]9, or a similar [illegible] on a modified principle, patented by Francis Virtue, [illegible]. In these machines, by mechanical contrivances, the [illegible] quantity of heated meal is placed in a trapeziform tray enclosed in a cloth and submitted to a pressure which reduces the thickness of the mass from about 3 inches to a little more than 1 inch and forms it into a solid cake, in which state it packs in small space in the press. The whole time occupied in filling and forming a cake and placing it in the press is not more than a quarter of a minute, and a set of three pack presses in a day of ten hours will work off nearly 9 tons of seed, yielding in the case of linseed about 108 cwt. of cake, and 54 cwt. of oil. It is claimed for the pack press that it extracts a much larger proportion of oil than that worked with seed-boxes.

Horizontal presses are not much in favour in the United Kingdom, but in many Continental mills where two pressings are the rule a set of horizontal presses are kept for the first operation.

The oil, during the process of pressure, works its way from the centre to the edge of the cake, whence it exudes. For this reason an oblong form is the most favourable for the easy separation of the oil, and the trapeziform shape oil-cakes usually present has been selected on account of the wedge-like steadiness the mass has under pressure, and the readiness with which the entire cake frees itself once it is moved the smallest distance from the thin end of the box or tray in which it is pressed. The edges to which the oil is pressed almost invariably retain a considerable proportion of oil. They are pared off, and the parings are returned to the edge-stones to be ground up and again pressed with fresh meal. The oil from the presses flows into the receiver tanks placed under the level of the floor, from which it is pumped into the storage tanks, where it is permitted to settle and clarify. After mechanical impurities and water, &c., have separated themselves, the oil is in some cases ready for the market, but for the most part it has to undergo a process of refining.

Extraction by Solvents.—The only method of obtaining vegetable oils which has come into practical competition with pressing is that in which the solvents bisulphide of carbon (CS_2), the light spirit of petroleum, and common ether are used. In ordinary pressing about 10 per cent. of oil remains in the finished cake, while by means of solvents practically the whole of the oil may be separated. Solvents might therefore be used for extracting that remaining percentage of oil from any oil-cake were such desirable, or they can be employed for treating fresh unpressed seed. As a matter of fact, it is desirable to leave a proportion of oil in the cake which is used for feeding purposes, because its food value depends to no small extent on the oil it contains, and the perfect separation of oil in the solvent process is a drawback, on account of the poverty in fatty matter of the exhausted meal.

Extraction by the agency of bisulphide of carbon was first introduced in 1843 by Jesse Fisher of Birmingham. Twelve years later a patent was secured by E. Deiss of Brunswick, but for several years afterwards the process made little advance. The colour of the oil produced was high, and its taste sharp; it retained traces of sulphur, which showed themselves disagreeably in the smell of soaps made from it, and in the blackening of paints in which it was used; and the meal left by the process was so tainted with evil-smelling carbon bisulphide that cattle would not taste it. These drawbacks have now been perfectly surmounted, and the process appears likely to come into extended use on the Continent.

The seed for treatment with bisulphide of carbon is prepared as for pressing, except that it is not reduced to a fine meal, which would prevent the percolation of the solvent freely through the mass. It is only bruised and placed in a series of four or five upright cylinders, which are hermetically closed and provided with a complicated arrangement of pipes leading to and from each other in various ways,—all being controlled by stop-cocks. Into the first cylinder A bisulphide of carbon is admitted from an overhead reservoir, till the whole mass is saturated with the fluid. After allowing the bisulphide to act on the contents of the cylinder for about fifteen minutes, communication between cylinders A and B is opened, the fluid from A passes into B, and a fresh supply of bisulphide comes from the reservoir into A. Again, after the lapse of fifteen minutes, the pipe leading into cylinder C is opened, and the fluid contents of B enter C. B is filled from A, which again is replenished from the reservoir. The extraction thus goes on, pure bisulphide of carbon always entering the weakest, most nearly exhausted cylinder, and passing on with gradually increasing percentage of oil to cylinders having more and more oil in their contents, till at the end, in the most recently charged cylinder the bisulphide is fully saturated with oil and passes off to the distilling apparatus, where the oil and the bisulphide are separated. When the contents of a cylinder have been fully extracted that vessel is isolated from the others, the remaining bisulphide of carbon is forced out by the admission of compressed air, and thereafter steam is run through the exhausted meal till not a trace of the solvent remains. The bisulphide, boiling at 46° C., is easily separated from the oil by simple distillation, and the last traces of the sulphur compound are removed by blowing steam through the oil in the distilling apparatus. Careful provision is made for the prevention of escape and for the recovery and proper storing of the bisulphide of carbon in use.

In addition to the use of bisulphide of carbon claimed under his patent of 1855 (English patent 1856), E. Deiss enumerates as solvents chloroform, ether, and benzin or benzol. In 1863 an English patent was secured by Messrs Richardson, Lundy, and Irvine for obtaining oil from crushed seeds, or from refuse pressed cake, by the solvent action of "volatile hydrocarbons from petroleum, earth oils, asphaltum oil, coal oil, or shale oil, such hydrocarbons being required to be volatile under 212° Fahr." Since that time the development of the American petroleum industry and improvements in the apparatus employed have raised this system of extraction to the rank of a competing practical method of oil production. The most approved apparatus for this method of extraction at present in use is that of Vohl. In the separation of oil from oil-seeds by means of light petroleum spirit heat is required. Vohl uses a light petroleum spirit boiling at not more than 60° C., which he calls canadol, and by a very ingenious arrangement of extractors, boiling and collecting kettle, and condenser, all brought into connexion by a system of pipes, he percolates the crushed seed in the extractor cylinders with heated canadol, which passes down into the kettle laden with extracted oil. Here the volatile canadol is distilled off by steam heat, and passes into the condenser, whence it again goes into the extractors, still further exhausting the seed and carrying an additional portion of fixed oil into the kettle. In this way the original charge of canadol keeps circulating till it completely exhausts the charge of seed in the extractors. The canadol is then distilled off from the fixed oil collected in the kettle, the condensed spirit going this time into a separate receiver, and finally the oil is perfectly freed from canadol by having steam blown through it. As pure petroleum spirit extracts neither resinous nor gummy matters from the oil-seed, and moreover takes up little or no colouring matter, the oil obtained by this solvent is remarkably pure, and the process is quite adapted for extracting even the oils used for food and for pharmaceutical purposes. The extraction of oils by means of ether, although presenting many advantages, has never been successfully undertaken on a commercial scale, chiefly through the apparently insurmountable waste of the costly menstruum.

Refining.—The refining of vegetable oils is generally carried on as a separate industry. A kind of clarification of an expressed oil takes place by simple settling in oil-tanks, but the action is too tedious and the result too imperfect for practical purposes. The all but universal method of oil-refining now practised was invented and patented by Charles Gower in 1792. It consists of treating the oil with a small percentage of sulphuric acid, which, owing to the avidity with which it takes up water, acts on the suspended impurities by depriving them of the water they contain, and then carbonizes the substances themselves, which precipitate in dark-coloured flocky masses. To a certain extent also the acid influences the oil itself, liberating fatty acids and combining with the freed glycerin; and these new products remain dissolved in the oil. It is thus of great importance to use no more than that proportion of sulphuric acid which is capable of separating the impurities. The ordinary operations of refining are briefly as follows. The oil is placed in a large tank, within which is a coil of pipe for heating by steam. When the oil is sufficiently hot, sulphuric acid is slowly added to the extent of from ½ to 1½ per cent. of commercial acid, according to the nature and impurities of the oil. After the contents of the tank have been in vigorous agitation for about an hour, it is left at rest for about five hours to allow the charred impurities to collect and precipitate. The oil is then conveyed into a washing vat, where it is mixed with about 20 per cent. of boiling water, with the addition of a little soda, and kept briskly stirred for an hour. From this the mixture passes to clearing tanks, in which the oil is allowed to rest about a week in order to thoroughly separate the remaining water. The addition of about 5 per cent. of common salt, by increasing the specific gravity of the water, considerably hastens this separation. Finally the oil is passed through a filter composed of alternate layers of tow, dried moss, canvas, and similar porous substances. Numerous modifications of the above sequence and other processes of refining have been introduced, and more or less adopted. One of the best distinct processes is that of Bareswil, which consists in heating the oil and adding to it 2 to 3 per cent. of caustic soda. Thereby a corresponding proportion of soap is formed, which, rising to the surface as a strong frothing scum, brings with it the impurities which are rendered insoluble. The scum is subsequently allowed to precipitate, in doing which it perfectly clarifies the oil. The coagulum so formed is used as a lubricant. Rudolph von Wagner proposed the use of concentrated chloride of zinc, instead of sulphuric acid, in refining; and various other mineral acids as well as salts and tannin have also been suggested and tried. The most recent process of refining, and certainly the simplest and most expeditious if experience demonstrates its sufficiency, is that introduced by Mayer of the Hernalser Actien-Oelfabrik. It consists simply in submitting oil direct from the press to the action of a centrifugal machine. Thereby the albuminoid, mucilaginous, and other impurities are driven against the sides of the drum, on which they deposit as a solid coating, leaving the oil pure and clear. The effect is, of course, due to the difference in density between the oil and its suspended impurities.

Animal Fat Rendering.—The animal fats, butter only excepted, are liberated from the cells in which the fatty matter is enclosed by the agency of heat alone. The heat applied melts the fat, and by thereby causing its expansion as well as by acting on the moisture in the tissue it bursts the cell membrane and allows the liquid fat to flow together. The process is a noxious and disagreeable one owing to the intolerable stench given off by the putrefying animal matter while under the influence of heat; and it is practically impossible to have the fatty matter heated on a large scale in its pure and sweet condition. It becomes an object of importance, therefore, to prevent the escape of such disagreeable fumes into the air, and the apparatus used is principally modified with that view. The simplest method of tallow-rendering consists in cutting the fatty matter by hand or machine into small fragments, which are placed in a copper vessel, with a small quantity of water, over an open fire. While the fire is applied the mass is kept stirring, and gradually the oil exudes and collects as the membranous matter—greaves or cracklings—becomes shrunken and shrivelled. The fat is then ladled out of the boiler and strained through a sieve or filter, and the greaves, placed in a hair or woollen bag, are submitted to pressure, by which a further portion of tallow is separated. The pressed greaves are useful for dog's food or for feeding swine, &c., or they may be still a source of tallow, which can be obtained by treating them with bisulphide of carbon or with petroleum spirit. An improved method of rendering tallow consists in crushing the suet under a pair of edge-stones, whereby the cells are ruptured, and heating the product over an open fire with about one-fifth part of water acidified with from two to seven parts of strong sulphuric acid added in the boiler. The means, however, of most effectually separating animal fat and at the same time avoiding the pollution of the air consists in the use of air-tight cylinders or kettles heated by steam. According to certain methods of working, superheated steam is forced into the kettle and acts direct on the shred suet, &c.; in other cases the steam circulates in a coiled pipe within the vessel; and a third way consists in the use of steam-jacketed rendering vessels. Strained tallow, however prepared, is further purified or refined before using by melting and thorough washing with hot water, after which it is allowed to cool slowly, so as to throw down impurities with the separating water. The same effect is also produced by blowing steam through molten tallow (comp. LARD, vol. xiv. p. 312).

Classification and Enumeration of Oils and Fats.

There is no strictly systematic plan upon which oils and fats can be satisfactorily classified and arranged. The scheme which follows brings the various commercial products into convenient groups, the distinctions of which are of prominent importance.

I. *Fluid Oils.*
   - *a.* Non-drying or greasy oils, containing chiefly olein.
   - *b.* Drying oils, containing linolein.
   - *c.* Fish or train oils, containing physetolein.

II. *Fats and Waxes.*
   - *a.* Solid glycerides, principally palmitin and stearin.
   - *b.* Non-glycerides or waxes.

In a pure condition the non-drying oils undergo little change through the influence of the atmosphere, but by degrees a process of slow fermentation is set up by the agency of the natural impurities they contain, developing an offensive rancid smell, and rendering the oils thick and greasy. Even in very thin layers, however, they never dry. Under the influence of nitrous acid and mercuric nitrate the olein of non-drying oils undergoes a molecular change into elaidin, and the oil becomes solid. Castor oil, the characteristic glyceride of which is ricinolein, occupies an intermediate position between drying and non-drying oils. The influence of nitrous acid on ricinolein changes the molecular constitution of the body forming ricinelaidin, with simultaneous solidification, as in the case of olein. The drying oils are those which contain as principal constituents linolein or analogous glycerides. They absorb oxygen from the atmosphere with much rapidity, giving off at the same time carbonic acid and water, whereby the composition of the oil is modified, the proportion of oxygen much increased, and the physical properties of the oils changed. They do not solidify under the influence of nitrous acid. The fish oils do not dry on exposure to the

air, but they thicken and present physical features intermediate between drying and non-drying oils.

The following list embraces the whole of the oils, fats, and waxes ordinarily met with in commerce. Such of them as are of considerable importance are indicated by an asterisk, and notices of these will follow or be found under their own headings, or under the name of the producing material. The oils, &c., of local, limited, or otherwise minor importance are marked with an obelisk.

Name of Oil.	Source.	Yield per cent.	Specific Gravity.	Principal Use.
1. Non-Drying Oils.				
*Ground-nut	*Arachis hypogæa*	38-50	0·918	Food; soap.
Ben	*Moringa pterygosperma*	30-35	0·912	Perfumery; personal.
*Almond	*Amygdalus communis*	45-55	0·915	Perfumery; medicine.
†Peach	*Amygdalus persica*	32-35	0·914	Perfumery; medicine.
†Plum-kernel	*Prunus domestica*	25-30	0·9127	Perfumery; medicine.
†Cherry-kernel	*Prunus Cerasus*	25-30	0·923	Food; burning; soap.
†Apple-seed	*Pyrus Malus*	12-15	..	Food; burning.
†Quince	*Cydonia vulgaris*	15	..	Food.
†Cashew	*Anacardium occidentale*	40-50	0·916	Food.
†Spindle-tree	*Euonymus europæus*	28-29	0·938	Burning; surgery.
†Horse-chestnut	*Æsculus Hippocastanum*	6-8	0·927	Medicine.
*Cotton-seed	*Gossypium* sp.	15-20	0·9266	Soap and lubricant.
Tea-seed	*Camellia theifera*	30-35	0·927	General use in China.
Brazil-nut	*Bertholletia excelsa*	60-67	0·9185	Food.
†Jungle-almond	*Terminalia Catappa*	28	0·918	Food.
*Colza	*Brassica campestris*	35-45	0·9150	Lighting.
*Rape	*Brassica campestris*, var. *Napus*	30-40	0·9130	Lighting and lubricant.
*Mustard	*Brassica* sp.	15-25	0·917	Soap-making.
Radish-seed	*Raphanus sativus*	45-50	0·917	Food.
*Sesame or Gingelly	*Sesamum orientale*	50-56	0·9235	Food; soap-making.
*Olive	*Olea europæa*	20-50	0·91	Food; burning, &c.
Beech-nut	*Fagus sylvatica*	20	0·9225	Food; burning.
Hazel-nut	*Corylus Avellana*	50-60	0·9243	Food; perfumery; burning.
Maize	*Zea Mays* (germ)	15	0·9215	Burning; wool; oiling.
†Cyperus-root	*Cyperus esculentus*	20	0·924	Food.
*Castor	*Ricinus communis*	50-60	0·9667	Medicine; soap; lubricant.
*Croton	*Croton Tiglium*	30-40	0·942	Medicine.
Purging-nut	*Jatropha Curcas*	30-40	0·915	Medicine; soap; lubricant.
Animal Oils—				
*Neat's-foot	...	..	0·915	Fine machinery oil.
Sheep's	...	..	0·9175	Fine machinery oil.
Horse	...	..	0·913	Fine machinery oil.
†Egg	Yellow of eggs	10-13	..	
2. Drying Oils.				
*Candle-nut	*Aleurites triloba*	55-60	0·940	Burning; paint; soap.
Wood	*Aleurites cordata*	35-41	..	Varnish and paint.
†Grape-seed	*Vitis vinifera*	10-20	0·9202	Food; burning; soap.
*Linseed	*Linum usitatissimum*	20-33	0·9350	Paint; varnish; linoleum, &c.
Pumpkin-seed	*Cucurbita Pepo*	20-25	0·9231	Food; burning
Koeme	*Telfairia pedata*	33	..	Food.
*German sesame	*Camelina sativa*	25-28	0·9235	Burning; soap
†Cress seed	*Lepidium sativum*	50-60	0·924	Burning; soap.
*Poppy	*Papaver somniferum*	50-60	0·9250	Food; paints; soap.
†Mexican poppy	*Argemone mexicana*	25-30	0·919	Burning; medicine.
†Weld-seed	*Reseda Luteola*	30	0·9358	Burning; paints.
†Belladonna	*Atropa Belladonna*	..	0·925	Food; burning.
†Tobacco-seed	*Nicotiana Tabacum*	30-32	0·9232	Burning.
*Sunflower	*Helianthus annuus*	28-30	0·9260	Food; paints; soap.
*Madia	*Madia sativa*	35-40	0·9286	Burning; soap; lubricant.
*Niger	*Guizotia oleifera*	40-45	0·9242	Soap; lubricant.
*Safflower	*Carthamus tinctorius*	30-35	..	Food; burning.
*Hemp	*Cannabis sativa*	30-35	0·9276	Lubricant; varnish.
*Nut	*Juglans regia*	40-50	0·9250	Food; oil-painting.
†Pine-tree	*Pinus sylvestris*	25-30	0·9312	Paints and varnishes.
†Red-pine seed	*Pinus Abies*	25-30	0·9255	Paints and varnishes.
3. Train and Fish Oils.				
Walrus	*Trichecus rosmarus*	..	0·9250	Burning; lubricant; currying leather, &c.
*Seal	Various species	..	..	Burning; lubricant; currying leather, &c.
*Porpoise	*Delphinus phocæna*	..	0·9220	Burning; lubricant; fibre dressing, &c.
*Bottle-nose	*Globiocephalus globiceps*	..	0·9180	Burning; lubricant; fibre dressing, &c.
*Sperm	*Physeter macrocephalus*	..	0·880	Lubricant.
*Whale	Various species	..	..	Burning, lubricant, &c.
*Cod	Livers of *Gadus morrhua*, &c.	..	0·925	Burning, lubricant, &c.
Shark	Livers of *Squalus*, various species	..	0·875	Medicinal; currying leather.
Fish	Various fish	..	..	Burning; lubricant.

Name of Oil.	Source.	Yield per cent.	Specific Gravity.	Principal Use.
4. Vegetable Fats.				
†Dika butter	*Irvingia Barteri*	60-65	0·820	Food; candles; soap.
†Java almond oil	*Canarium commune*	40	..	Food.
*Chinese vegetable tallow	*Stillingia sebifera*	20-30	0·918	Candles; soap.
Pekea butter	*Pekea butyrosa*	..	..	Food.
Soap-tree oil	*Sapindus emarginatus*	30	..	Soap-making.
Carapa oil	*Carapa guyanensis*	60-70	..	Soap; medicine.
Piney tallow	*Vateria indica*	..	0·9150	Candles.
Borneo tallow	*Hopea macrophylla*	..	..	....
*Cocoa butter	*Theobroma Cacao*	..	..	....
†Cokum butter	*Garcinia indica*	10	..	....
†Chaulmoogra oil	*Gynocardia odorata*	30	..	Medicine.
*Oil of mace	*Myristica moschata*	20-23	0·990	Medicine; perfumery.
†Otoba butter	*Myristica Otoba*	..	..	Medicine; candles.
†Becuiba tallow	*Myristica Bicuhyba*	..	..	Medicine; candles.
*Shea butter	*Bassia Parkii*	40	0·953	Candles; medicine.
*Ghee butter	*Bassia butyracea*	..	..	Food; medicine.
†Mahwa butter	*Bassia latifolia*	35-40	0·972	Soap; candles.
†Bayberry oil	*Laurus nobilis*	..	..	Veterinary medicine.
†Avocado oil	*Persea gratissima*	..	..	Soap.
*Palm oil	*Elæis guineensis*	..	0·945	Soap and candles.
*Palm-seed oil	*Elæis guineensis*	45-50	0·952	Soap and candles.
*Cocoa-nut oil	*Cocos nucifera*	..	..	Soap and candles.
5. Animal Fats.				
*Lard	*Sus scrofa domestica*	..	0·940	Food; candles; lubricant.
Horse fat	*Equus caballus*	..	..	Currying; lubricant.
*Butter	Milk of Ruminants	..	..	Food.
*Tallow (ox)	*Bos taurus*	..	0·920	Soap; candles; lubricant.
Beef marrow	*Bos taurus*	..	..	Pomade.
*Tallow (sheep)	*Ovis aries*	..	0·913	Food; soap; candles.
Goose fat	*Anas anser*	..	..	Pomade.
6. Waxes.				
a. Vegetable—				
*Japanese wax	*Rhus succedanea*	..	1·006	Candles.
Ocuba wax	*Myristica Ocuba*	..	0·920	Candles.
Cow-tree wax	*Galactodendron americanum*	..	..	Candles.
Myrtle-berry wax	*Myrica cerifera*	20-25	1·005	Candles.
Carnahuba wax	*Corypha cerifera*	..	0·995	Candles.
Palm-tree wax	*Ceroxylon andicola*	..	0·995	Candles.
b. Animal—				
*Beeswax	*Apis mellifica*, &c.	..	0·963	Candles, &c.
*Insect wax	*Coccus ceriferus*	..	0·970	Candles, &c.
*Spermaceti	*Physeter macrocephalus*	..	0·943	Candles; surgery.

Oil Testing.—The presence of mineral oils in any fixed oil is easily detected by the process of saponification, as well as by a peculiar fluorescence they impart to the mixture. In the saponification test the oil is made into a soap, with either soda or potash, the product mixed with sand, and the whole treated with light solvent petroleum spirit, which extracts the mineral oil. The increase in quantity of solution over the solvent used is the measure of the proportion of adulterants in the oil. Smell, taste, specific gravity, and viscosity, all to a certain extent give indications of the nature of an oil. The elaidin proof—that is, the solidification or non-solidification of an oil under the influence of nitrous acid, and the length of time required for solidifying when such a change ensues—is a valuable indication of the nature of an oil; and similar trustworthy conclusions may be drawn by observing the heat developed by mixing one part of sulphuric acid with three parts of the oil to be tested, a test first suggested by Maumené, and elaborated by Fehling. The colour reactions which result from treatment with acids of different strengths, mixed acids and alkalis, &c., are the most important tests. The following tabular statement of several such tests is extracted from Schaedler's *Technologie der Fette und Oele* (Berlin, 1883). The first column shows the colour reactions produced by nitric acid of sp. gr. 1·18 to 1·20 on equal proportions of oil; the second the effect of fuming nitric acid of sp. gr. 1·40 to 1·45 on four or five times the amount of oil; the third the colour reaction from the use of sulphuric acid of sp. gr. 1·60 to 1·70; and the fourth the effect of a diluted mixture of nitric acid and sulphuric acid on equal volume of oils. In the fifth column is given in hours the time a non-drying oil takes to solidify under the influence of nitrous acid, after which comes the appearance of emulsions formed by treatment with alkaline leys of 1·33 sp. gr. The last two columns are devoted to the effects produced by a solu-

tion of chloride of zinc and of hydrochloric acid with the addition of about 2 per cent. of sugar.

Commerce.—As regards the United Kingdom it may be said in general terms that Hull is the centre of the linseed and other seed oil trade, Liverpool the headquarters of that in palm oil and palm-nut oil. Tallow and lard and sperm, train, and fish oils are dealt in principally in Dundee, London, and Greenock. In the Mediterranean Marseilles and Trieste are oil-trading centres of great importance, and Hamburg, Rotterdam, Antwerp, and Copenhagen are busy oil marts in northern Europe. Sperm oil, lard, and animal oils come to British markets most largely from the United States, tallow from South America and Russia, castor oil from the East Indies and Italy, olive oil from Italy, the south of France, and Mediterranean ports generally. Palm oil is received exclusively from the west coast of Africa, and cocoa-nut oil from the East Indies and Ceylon. Of seeds imported as sources of oil, linseed is principally derived from the East Indies and Russia, cotton seed from Egypt, and rape from Russia and the East Indies. The following table, from the Board of Trade Returns, gives the imports and exports of oils and fats into the United Kingdom for 1882:—

	Imports.		Exports.	
	Quantities.	Value.	Quantities.	Value.
1. Oils and Fats.				
Fish, train or blubber	14,303 tuns	£420,466	1,624 tuns	£49,052
Sperm or head matter	1,642 tuns	111,197	119 tuns	8,053
Animal	67,877 cwts.	157,617	9,958 cwts.	25,714
Castor	163,970 cwts.	264,551	24,288 cwts.	40,057
Cocoa-nut	133,782 cwts.	210,054	134,368 cwts.	205,788
Olive	23,450 tuns	947,154	3,668 tuns	166,693
Palm	813,870 cwts.	1,240,866	428,162 cwts.	642,203
Seed	14,507 tuns	476,807	1,162 tuns	37,279

Subjoined are notices of various oils and fats of considerable commercial importance to which special articles are not devoted in other parts of this work. In several cases notices of oils will be found under special headings, incorporated with descriptions of other products of the plants and animals whence they are obtained. Here drying and non-drying oils are dealt with together in alphabetical order, after which vegetable fats and animal oils and fats are noticed in groups.

1. *Liquid Vegetable Oils.*—*Almond oil*, the produce of both the sweet and the bitter almond, is a pale straw-coloured oil, having a pleasant nutty taste and sometimes—when pressed from bitter almonds—an odour of the essential oil of bitter almonds. The oil consists almost entirely of olein, remains fluid to −15° C., and solidifies at 20° C. It is used in food, and in medicine is employed as a demulcent and mild laxative; but the readiness with which it becomes rancid interferes with its free use in these capacities. It produces a fine firm soap, and is also largely used by perfumers. The oil is much adulterated with the allied peach-kernel oil, and sesame oil, nut oil, &c. It is chiefly expressed in England from almonds imported from the Mediterranean and the East Indies. *Peach-kernel oil* (from *Amygdalus persica*), *Apricot oil* (from *Prunus armeniaca*), *Plum oil* (from *P. domestica*), and *Cherry oil* (from the kernels of species of *Cerasus*) are a series of oils allied both in sources and properties frequently mixed with or sold as almond oil. *Ben oil* is obtained from the seeds of *Moringa pterygosperma* and *M. aptera*, trees native of Egypt, Syria, and the East Indies, and cultivated in America. The oil, cold-drawn, is clear, bland, and odourless, with little tendency to rancidity, but the product of final hot pressing is coloured, and has a bitter taste and purgative properties. The oil contains, in addition to palmitin, stearin, and olein, the glycerides of behenic acid $C_{22}H_{44}O_2$, and myristic acid $C_{14}H_{28}O_2$. Ben oil is used by perfumers for obtaining essential oils by enfleurage, as a hair oil and ointment, as a salad oil in the West Indies, and as a lubricant for watches and small machinery. It is, however, principally consumed in the regions of its production. *Candle-nut oil* is obtained from the nuts of *Aleurites triloba*, a tree native of the South Sea Islands, but grown also generally throughout tropical countries. The nuts are about the size of a horse-chestnut, with kernels which yield as much as from 60 to 66 per cent. of oil. The name given to these fruits is due to the fact that they are used in the Sandwich Islands, spitted on a stick, as lamps or candles, in which condition they burn with a clear steady light. The oil, cold-pressed, is a clear, almost colourless, rather viscid fluid, with a pleasant taste and smell, and medicinal properties akin to those of castor oil. Hot-pressed, it has a brown colour and a rather disagreeable odour and taste. It contains glycerides of linoleic acid and myristic acid in addition to those of palmitic acid and oleic acid, and possesses strong drying properties which make it useful for varnishes, and otherwise as a substitute for linseed oil; it is also an excellent illuminant and a valuable soap-making material. On account of the cheapness of linseed oil, and the superior value of linseed cake, candle-nut oil does not find a very extensive market in Europe, but it is the basis of an industry of some importance in the South Sea Islands, whence a large quantity of the oil is annually exported to the west coast of America. The nuts of *Aleurites cordata* yield *Wood oil*, a powerfully drying oil, of much importance in China and Japan for use as a natural varnish and in medicine. It does not enter into Western commerce. *Cotton-seed oil*, obtained from the decorticated seed of the varieties of cultivated cotton, is now, on account of the enormous extent of its production, one of the most important of the fluid vegetable oils. Its preparation is quite a recent industry, dating only from 1852, when the first importation of the material was made from Egypt. Since that period the trade has developed with extraordinary rapidity. *Egyptian seed*, containing about 25 per cent. of oil, is chiefly pressed in European countries (England, France, Germany); the American seed pressed in the United States shows not more than 20 per cent. of oil. The oil as expressed has a dark-brown turbid appearance, owing to the presence of a resin with albuminous impurities, and in the early days of the industry much difficulty was experienced in refining the product sufficiently for commercial purposes. It is now purified by as far as possible coagulating and separating the impurities by treatment with boiling water and steam. After the coagulum so formed has precipitated and been separated, the oil is treated with weak alkaline ley, briskly agitated, and allowed to settle, when the coloured resinous matter goes to the bottom; over that comes a proportion of saponified oil, and the clear refined oil forms the upper portion. The refined oil has a clear straw-yellow colour, a faint earthy odour, and a pleasant nut-like flavour. It consists entirely of a mixture of palmitin and olein, the former beginning to solidify and separate out between 12° C. and 6° C. There is no doubt that cotton-seed oil is very extensively and generally used to adulterate other and more costly oils, especially olive oil. It also is largely used in soap-making, and it constitutes a principal ingredient in compound lubricating oils. The quantity of cotton seed available for pressing annually is estimated to be not less than 800,000 tons, from which about 120,000 tons of oil and 250,000 tons of oil-cake may be produced. *German Sesame* or *Cameline oil* is procured from the small yellow or ruddy seeds of the cruciferous plant called Gold of Pleasure, *Camelina sativa* (*Myagrum sativum*, Linn.). The oil has a golden-yellow colour, a distinctive smell, and a somewhat sharp taste. In addition to other glycerides it contains that of erucasic acid, and of some analogue of linoleic acid. The oil dries

only slowly on exposure to the air, and its chief applications are found in soap-making and for burning in lamps. It is principally produced and consumed in Germany and Russia. *Grape-seed oil* is used in the south of Germany and north of Italy for food and for burning in lamps. The seeds yield from 10 to 20 per cent. of a pleasant brownish-yellow very fluid oil, which dries very slowly on exposure to the air. *Ground-nut oil* (see GROUND NUT) is an excellent edible oil, largely used as a substitute for olive oil, and to no small extent passing into consumption either separately or mixed with olive oil under the name of the latter. The inferior hot-pressed qualities are employed in soap-making, being a principal staple of the soap industry of Marseilles, into which city not less than from 700,000 to 800,000 tons of the nuts are annually imported from West Africa. *Madia oil* is obtained from the fruit of *Madia sativa*, a plant native of Chili, but introduced into Europe within this century on account of its oil-yielding properties. The seeds contain from 35 to 40 per cent. of a dark-yellow oil, of peculiar smell and mild taste, which has a tendency to become rancid. It has only faint drying properties, and occupies a place intermediate between drying and non-drying oils. When cold-pressed, madia oil may be used for food purposes, but it is principally consumed in lamps, or employed as a lubricant and in soap-making. *Maize oil* is a product of the seed-germs, which, in the preparation of maize meal and starch and fermented and distilled liquors from maize, have to be removed as carrying in them a disagreeable acrid substance. The germ contains about 15 per cent. of a clear golden-yellow oil, useful for burning, or oiling wool, and for lubricating machinery. *Niger oil* is the produce of the seeds (properly achenes) of *Guizotia oleifera*, a plant native of the east coast of Africa, but cultivated throughout India and to some extent in Germany. The fruits, which are small, tooth-like in form, and shining black in colour, contain from 40 to 45 per cent. of oil, which first came into the English market about 1851. The oil is limpid, clear, pale-yellow in colour, with a pleasant nutty mild flavour. It possesses little drying property, and is not fitted for use either in paints or varnishes. It is much used in India—in the Deccan especially—as a substitute for ghee with the poorer sections of the population, and in other parts of the country both as a culinary oil and for burning. In Western countries niger oil is principally employed in soap-making and as a lubricant. *Nut oil* is the produce in Europe of the nuts of the walnut tree, *Juglans regia*, and in America a similar oil is obtained from hickory nuts, *Carya alba*. The European walnut kernels yield from 40 to 50 per cent. of a fine limpid oil, which when cold-pressed is almost colourless, with a sweet nutty taste and pleasant odour, but the hot-pressed oil has a greenish-yellow colour and a rather sharp taste. Nut oil consists in large proportion of linolein, with olein and the glycerides of myristic and lauric acid. It is one of the most fluid of all oils, and, as it possesses with colourlessness strong drying properties, it is much valued by artists for oil-painting; it also yields a fine transparent varnish. In the hilly districts of northern India and Persia—the native regions of the walnut—the oil is used for culinary purposes and for lighting. Several closely-allied nuts, both in Europe and in America, yield oil similar in quality to that of the walnut. *Para-nut* or *Brazil-nut oil*, yielded by the kernels of *Bertholletia excelsa*, is employed in South America as a food-oil and for soap-making. To a limited extent it is also pressed in England and Germany from nuts which become unfit for table use. The oil becomes rapidly rancid. *Sapucaia oil*, yielded by *Lecythis ollaria*, also a South-American tree, allied to the *Bertholletia*, is analogous in properties and uses. *Pine oils* are got from the seeds of various species of pine and fir trees containing some proportion of resinous matter; they have a turpentine odour and possess powerful drying properties. They are useful for mixing painters' colours, for making varnishes, and for burning in lamps. *Poppy oil* is yielded by the seeds of the opium poppy (see OPIUM). In the valley of the Ganges, the great region of opium culture, the poppy seed is consumed as an article of food by the native population, and is their principal source of oil. The exceedingly minute seeds contain as much as 60 per cent. of a fine transparent, nearly colorless limpid oil, of pleasant taste and faint characteristic odour. The qualities obtained by cold and hot pressing respectively are distinguished from each other, the former being an esteemed salad oil, while the latter, of yellow colour, sharp taste, and linseed-oil-like odour, is used for soap-making, &c. Poppy oil consists principally of the glyceride of linoleic acid, linolein, and has therefore powerful drying properties, on which account it is much used by artists. To some extent the finer qualities are used for adulterating olive oil. *Purging-nut oil* is obtained from the seeds of *Jatropha Curcas*, a small tree native of India, but cultivated in tropical countries. It is a violent purgative, and contains, like castor oil, ricinoleic acid. It is comparatively limpid and odourless, and forms an excellent lamp oil. It is also used in the soap trade and as a lubricant. *Safflower oil* is yielded by the seeds (achenes) of the composite plant *Carthamus tinctorius*, which contain from 30 to 35 per cent. of a light-yellow clear limpid oil. It is extensively used in Egypt, the East Indies, and China (where the plant is cultivated as a source of the dye-stuff safflower); its principal applications being for culinary purposes and burning, and also as an ointment in paralytic affections and ulcers. A thick sticky charred oil is obtained from the seed in India by a process partly of burning and partly of distillation. The dark fluid so obtained is used by the native agriculturist for greasing leather-work exposed to the action of water. *Sesame* or *Gingelly oil*, one of the most highly esteemed of vegetable oils, is the produce of *Sesamum orientale*. The plant is grown especially in India as an annual; it ripens in about three months, and two crops are reaped yearly. The seeds are very small, weighing not more than one-tenth of a grain, and they vary in colour from a dirty white through brown to nearly black. They are highly oleaginous, containing as much as from 50 to 56 per cent. of a clear limpid oil of a pale-yellow colour, inodorous, bland and sweet of taste, and not liable to rancidity. It consists of about three parts of olein to one part of stearin and palmitin, with a small proportion of the glyceride of myristic acid; and it does not solidify till it reaches 5° C. Both seed and oil are of much importance in the East Indies and China as food substances. The seed itself is used directly as food; the oil comes next to cocoa-nut fat in the variety and extent of its applications for food, personal use, and soap-making; and the pressed cake is even an article of food among the poorer classes. As a salad oil the cold-pressed qualities are in every respect equal to the finest olive oil, its mild piquancy of taste causing it to be preferred by many. Indeed sesame oil may be used with advantage for every purpose to which olive oil is applied, excepting, probably, the Turkey-red dyeing, and it is in extensive consumption in food, lighting, soap-making, and as a lubricant. The oil is the subject of much adulteration, especially with the cheaper ground-nut oil. It can by itself, or as an adulterant of olive oil, be readily recognized by a peculiar green coloration it takes when shaken up with mixed sulphuric and nitric acids, a reaction peculiar to sesame oil. Sesame seed is principally crushed at Marseilles and Trieste, to which ports it comes partly from the Levant, but more largely from the East Indies and Java. The quantity of seed imported into France alone yearly is not less than from 70,000 to 80,000 tons. *Sunflower oil* is a clear pale-yellow limpid oil, with scarcely any smell and a mild pleasant characteristic taste, obtained from the so-called seeds (achenes) of the sunflower plant, *Helianthus annuus*, which yield when freed from their husk about 30 per cent. of the oil. It contains glycerides of acids allied to linoleic acid, and possessing certain drying properties. It is of much importance in the east of Russia as an article of food, the sunflower being extensively cultivated in the government of Saratoff solely for its oil seed. *Tea-seed oil* is a commercial product in China, where it is used for food, lighting, and soap-making. It is said to yield a fine hard soap. The oil contains 75 per cent. of olein and 25 parts of stearin, has a yellow colour, and is destitute of taste and smell.

2. *Vegetable Fats.*—Among the numerous solid oils of the vegetable kingdom only a very few occupy a place of great importance in Western commerce. Those which hold a foremost position—palm oil, palm-nut oil, and cocoa-nut oil—are referred to under their proper headings. Of the others the following enter more or less into general commerce. *Dika butter* is a solid fat yielded by the drupes of *Irvingia Barteri*, a tree native of the Gaboon coast of Africa. The kernels are bruised and pounded into a cake, which is used by the natives for food as dika bread, and they contain more than 60 per cent. of solid oil, which can be separated either by boiling or by pressure with heat. It consists principally of glycerides of lauric and myristic acids, with only a little palmitin. Dika fat is used in soap and candle making. *Chinese tallow* is a white hard fat formed on the surface of the seeds of the tallow tree, *Stillingia sebifera*, native of China, but introduced into the North-West Provinces of India. The tallow is in China separated by steaming the seeds till they become soft, beating with stone mallets, and straining the mass through hot sieves. The fat melts at 44°·5 C., and consists principally of palmitin with only a little olein. Chinese tallow has long been valued in China for making candles used in Buddhist worship, and it is now an article in English commerce, being imported for candle and soap making. The seeds themselves, after separation of the fat, yield an oil fluid at ordinary temperatures. *Carapa* (or *Crab-wood*) *oil* is a soft white fat obtained from the seeds of *Carapa guyanensis*, a tree native of Brazil and Guiana and of the west coast of Africa. A similar fat is also expressed from the seeds of the allied *C. moluccensis*, from the coasts of India and Ceylon. The fat has a slightly aromatic odour and a powerfully bitter taste, said to be due to the presence of strychnine. It is imported into the European markets for soap-making, and in its native regions it possesses a great reputation as an ointment in rheumatic affections. *Piney tallow* is a hard solid fat obtained from the seeds of the Indian copal tree, *Vateria indica*. The substance has a feeble but pleasant smell, and a slightly yellow colour; it melts at 36°·5 C., and consists of three parts palmitin and one part olein. It is prized for candle-making on account of the pleasant odour given off by the glowing wick. *Cokum butter* is a solid white or greenish-yellow, pleasant-smelling, rather friable fat obtained from

the seeds of *Garcinia indica*, a tree native of western India. It contains, besides stearin and olein, the glyceride of myristic acid, and various free fatty acids of the volatile class. It is principally used in India to adulterate ghee, and for various medicinal uses; but it is described as forming an excellent substitute for spermaceti and to be applicable for soap-making. The seeds of *Garcinia pictoria* and other allied species yield a similar fat. *Oil of mace* is the solid oil obtained from the NUTMEG (*q.v.*). *Shea butter*, the fat of the seeds of the tropical African tree *Bassia Parkii*, is at ordinary temperatures of a buttery consistency, with a dirty or greenish-white colour and a pleasant aromatic odour and taste. It consists principally of stearin and olein, and is an important article of food in the basin of the Niger and the adjoining regions. In European commerce it is employed for soap and candle making and in the preparation of pomades. *Ghee* or *Indian butter*, the solid fat obtained from the seeds of *Bassia butyracea*, an allied tree native of the sub-Himalayan ranges of northern India, is a most important food substance among the natives of the North-West Provinces, possessing a delicate white colour, the consistency of lard, and a pleasant odour and taste. In the hot climate of India it will keep many months without acquiring bad odour or taste, on which account it is highly valued not only for food but also as an ointment, when perfumed, by the wealthier classes. It makes excellent soap and candles. *Mahua butter*, obtained from the seeds of *Bassia latifolia*, a tree cultivated generally throughout India, is used as a substitute for or as an adulterant of ghee. It possesses a greenish-yellow tinge, and becomes rancid more readily than genuine ghee. The fat is imported into England for soap and candle making. The seeds of *Bassia longifolia* and *B. elliptica*, natives of India, yield similar fats. *Bayberry oil* is the fat obtained from the seeds of the common bay or sweet laurel. It possesses a buttery granular consistence, a yellowish-green colour, a strong aromatic flavour, and a sharp bitter taste, due to the presence of an aromatic oil. It is pressed from the seeds principally in the south of Europe, Switzerland, and Holland, and finds its chief application in veterinary practice. *Avocado oil* is the produce of the fruit of the avocado pear tree, *Persea gratissima*, an edible fruit, native of the West Indies, but transported to other tropical regions. The fat consists of 30 per cent. of olein and 70 per cent. of lauro-stearin and palmitin, and is largely used in America for soap-making. In addition to the cocoa-nut palm and the oil palm, a large number of trees belonging to the same order, *Palmaceæ*, yield useful fats, which, however, are little known in ordinary commerce.

3. *Animal Oils*.—The only liquid animal oil of considerable importance other than the marine oils is *Neat's-foot oil*, a preparation from the feet of the common ox. For obtaining it the feet are split up and boiled in water over an open fire, or, preferably, treated with superheated steam in a closed cylinder. The oil is skimmed from the surface of the decoction, and after some time it deposits a thick greasy fat, from which the liquid portion is separated. Neat's-foot oil has a brownish colour and a mild animal taste and odour, and does not readily become rancid. It is very valuable for watchmakers' purposes, and for oiling fine machinery generally, and is in great demand in connexion with the tools and machines of engineers. It is much adulterated, generally with fish oils. A large quantity of ox-foot oil is prepared in and exported from the River Plate region in South America. *Sheep's-foot oil* and *Horse-foot oil* are made to a limited extent, and sold as neat's-foot oil. *Egg oil* is obtained as a by-product of the preparation of egg albumen from the yolk or yellow of hens' and ducks' eggs. It is extracted either by pressure or by ether from the hard-boiled yolks, and has a fine brownish-yellow colour and a mild taste, except when extracted by ether, which brings with it a disagreeable fatty constituent. It is now being used to a considerable extent in place of olive oil in the manufacture of chamois or shamoy leather. The *Seal oil* of commerce is obtained from the bodies of nearly thirty species of SEAL (*q.v.*). The blubber or fat consists of a layer of variable thickness lying between the skin and the muscular tissue. Skin and blubber are first removed together from the carcases of the animals, and when the products are landed the fat is removed from the skin and reduced to oil, either by slow maceration and exudation in large vats or by rendering with steam. When heaped up in great wooden vats the mere pressure of the mass causes a flow at first of a fine clear oil, which is saved as a separate commercial quality known as "pale seal." Fermentation and putrefaction meantime progress in the mass, which begins to give off an almost unbearable stench, and the exuding oil gradually assumes a dark-brown colour, with a disagreeable animal odour and taste. By degrees the exudation of oil ceases, and finally the remaining oil is obtained by boiling up the mass with fatty muscular scraps, the product of which also forms a separate class of seal oil. The oil rendered by the action of steam heat on the fat has the advantage of being promptly obtained, free from the disagreeable odour of the greater portion of the seal oil obtained in open vats. According to its quality seal oil varies in specific gravity from 0·915 to 0·930; at a temperature of 5° C. a proportion of stearin solidifies out, and at − 2° to − 3° C. it entirely solidifies. In chemical composition it consists principally of a glyceride of physetoleic acid with proportions of the glycerides of stearic acid, palmitic acid, a little oleic acid, and traces of some of the volatile acids. The oil is only very slightly soluble in alcohol, a circumstance which affords a means of detecting adulterations. It is used for the various purposes to which the allied whale oils are applied; regarding these see WHALE. *Shark oil*, obtained from the liver of various species of shark, is analogous in properties and applications to COD-LIVER OIL (*q.v.*). Shark oil is distinguished from all others by its low specific gravity, which ranges from 0·870 to 0·880. It contains, but in different proportions, the same constituents as cod-liver oil; particularly it is rich in iodine; and it possesses a peculiar, highly-disagreeable odour and a very acrid taste. Under the name of *Fish oil* may be embraced the oil obtainable by boiling from the refuse of various fish as well as from the entire fish which may for any reason be unfit or not applicable for human food. Such oils have a fishy odour and taste, a brownish colour, and a specific gravity ranging from 0·925 to 0·930. The most important of these products is *Menhaden oil*, obtained from the MENHADEN (*q.v.*) on the west coast of North America.

4. *Animal Fats*.—The few solid animal fats which enter into commerce are articles of such importance that they have special articles devoted to them (see LARD, vol. XIV. p. 312, and TALLOW), or of so little consequence that they do not demand special notice. Bear's grease, beef marrow, and goose fat are highly valued for use in pomades for the hair, but comparatively little of what passes under these names is obtained from the sources to which they are attributed.

5. *Waxes*.—The waxes of both animal and vegetable kingdoms will be dealt with under the heading WAX.

ESSENTIAL OILS.

The essential or volatile oils constitute a very extensive class of bodies which possess in a concentrated form the odour characteristic of the plants or vegetable substances whence they are obtained. The oils are usually contained in special cells, glands, cavities, or canals within the plants, either in a separate condition or intermixed with resinous substances, and in the latter case the mixtures form oleo-resins, balsams, or resins, according as the product is viscid or solid and hard. A few do not exist ready formed in the plants whence they are obtained, but result from chemical change of inodorous principles,—examples of this class being oil of bitter almonds and essential oil of mustard. Essential oils are for the most part insoluble, or only with difficulty and sparingly soluble, in water; but in alcohol, ether, the fatty oils, and mineral oils they dissolve freely. They ignite with great ease, and burn with a fierce smoky flame, depositing a large amount of carbon. In many important respects they differ from the fatty oils: they are not oleaginous to the touch, and make no permanent grease spot; they distil at various temperatures unchanged; they have an aromatic smell and hot burning taste; and in chemical constitution they present no relationship to the fats and oils.

Crude essential oils are at ordinary temperatures nearly all limpid liquids, but some are viscid; and the essential oil or otto of roses is solid. Many on exposure to low temperatures separate into two portions, one solid, called "stearoptene," the other liquid, called "elæoptene." The essential oils possess high refractive power. Their influence on the plane of polarized light is various: some rotate to the right, others give left-handed rotation, while with several no effect is visible. In their fresh condition many are colourless, but some are yellow or brown, others become brown by exposure, and in exceptional instances oils are green or blue in colour. They are all powerfully acted on by oxygen, which affects their colour, consistency, odour, and constitution. In specific gravity they range from about 0·850 to 1·142, most of them being specifically lighter than water, and averaging 0·90. In chemical constitution the essential oils are diverse, but they are invariably rich in carbon. They consist, first and principally, of hydrocarbons, associated with which generally are, secondly, oxygenated compounds, sometimes the product of oxidation of the hydrocarbons, although in many

instances there is no obvious relation between the bodies. A third class of essential oils, limited in number, consists of those into the composition of which sulphur enters. Of the hydrocarbons which constitute the principal proportion of essential oils terpene, $C_{10}H_{16}$, is the most important. Terpene is the chief constituent of the various kinds of oil of turpentine; and a hydrocarbon of precisely the same composition is contained in the oils of bergamot, orange, and other species of *Citrus*, and in a great number of other essential oils. But although agreeing in chemical formula these terpenes differ considerably in physical properties, such as specific gravity, boiling point, and rotatory influence on the plane of polarization. Under the name of terpenes are also included two series of hydrocarbons, polymeric with the $C_{10}H_{16}$ series, having respectively the formulæ $C_{15}H_{24}$ and $C_{20}H_{32}$. The former of these, $C_{15}H_{24}$, is of comparatively frequent occurrence, being found in the essential oils of cloves, cubebs, patchouli, and several others. The terpenes of formula $C_{10}H_{16}$, by their oxidation in presence of water, give off indirectly peroxide of hydrogen, H_2O_2, and yield cymene, $C_{10}H_{14}$, a hydrocarbon found naturally in the essential oils of cumin, thyme, and some others. The property of evolving peroxide of hydrogen, possessed by cymene in common with terpene, explains the well-known oxidizing and antiseptic influence of common turpentine oil, and has been turned to account in the preparation called "sanitas," a disinfectant and antiseptic agent, consisting of an aqueous solution of oxidized turpentine oil prepared by blowing air into a mixture of turpentine oil and water. The oxygenated bodies in essential oils when formed by direct oxidation of the hydrocarbon generally have feebly acid properties developing through viscid oleo-resins and balsams into solid resins. The oxygenated compounds are very varied in their constitution, some being of the nature of acids or aldehydes, while others exhibit the characters of alcohols or of ethers. The most characteristic oxygenated compounds in essential oils are camphors, the type of which is common or Japan camphor, $C_{10}H_{16}O$. Compounds isomeric with common camphor occur in the volatile oil of *Pyrethrum parthenium*, wormwood, mint, and other labiate plants, and in chamomile and galbanum. Camphors isomeric with Borneo camphor, $C_{10}H_{18}O$, are found in coriander oil, cajeput oil, and Indian geranium oil. Isomeric camphors having the formula $C_{10}H_{20}O$ form the menthol of peppermint and the eucalyptol of *Eucalyptus Globulus*, and patchouli camphor has the composition $C_{15}H_{26}O$. The other oxygenated bodies in crude essential oils mostly ally themselves with compounds of the aromatic series, so called on account of the large proportion of its members that are represented by natural products obtained in essential oils, balsams, and resins. The essential oils which contain sulphur, of which the allyl sulphide, $C_6H_{10}S$, or oil of garlic is a type, have generally a pungent, penetrating, and disagreeable odour.

The essential oils are obtained from their sources in four principal ways,—by distillation, by expression, by enfleurage or absorption, and by maceration. The process of *distillation* is the most important, and is applicable to a large number of substances owing to the ease with which essential oils distil unchanged. Their general insolubility in water is turned to account in the process, the odoriferous materials being placed in a simple still with a small quantity of water, the steam from which carries over with it the vapour of the essential oil. In distilling from certain bodies it is necessary to cohobate or return into the still the first distillate, and that operation may require to be repeated more than once before the raw material is quite exhausted. Again, in dealing with some substances, solutions of common salt or of chloride of calcium must be used in place of pure water, and these, by raising the boiling point, send over the vapour more richly laden with essential oil. After condensation and resting a sufficient time, the distillate separates into two portions, the oil floating or sinking according to its specific gravity. The process of *expression* is applicable to the obtaining of the essential oils which reside in the rind of the orange, lemon, and other citric fruits. *Enfleurage* is a method by which the odours of several substances are dealt with. The aroma in such cases is present to a small extent, and is too tender and liable to loss and deterioration to permit of being separated by way of distillation. The process consists of exposing the flowers in contact with purified lard or with fine olive oil in suitable frames, whereby the fatty substances take up and become impregnated with the essential oil. The process is principally employed in preparing pomades and perfumed oils (see PERFUMERY), as is also the analogous method of *maceration*, which consists in extracting the aromatic principles by macerating the raw materials in heated oil or molten fat, whereby the essential oils dissolve out into the fat. By subsequently digesting the impregnated fats and oils prepared either by enfleurage or maceration with spirit 60° over proof the essential oils are obtained as alcoholic essences, in which form they are much used for perfumery and flavouring purposes, &c. Alcoholic solutions of essential oils prepared by macerating the raw materials in alcohol also form a part of the tinctures of pharmacy.

Essential oils have a wide range of uses, of which the principal are their various applications in perfumery. Next to that in many ways they play an important part in connexion with food. The value of flavouring herbs, condiments, and spices is due in largest measure to the essential oils they contain; and, further, the commercial value of tea, coffee, wine, and other beverages is largely dependent on the delicate aroma which they owe to minute quantities of such oils. For the flavouring of liqueurs, of aerated beverages, and of other drinks essential oils are extensively used, and their employment is not less considerable in the manufacture of confectionery and in the preparation of many dietetic articles. In the cheaper kinds of confectionery a large quantity of artificial oils called fruit essences are now employed, although the flavours as such are distinctly crude, and the wholesomeness of the preparations is more than doubtful. The acetate of amyl gives an imitation jargonelle-pear flavour; valerate of amyl yields apple flavour: a mixture of butyrate of ethyl and butyrate of propyl gives the so-called pine-apple flavour. Formic ether has a peach-like odour, and is used for flavouring factitious rum, and there are numerous other artificial compounds used in flavouring and in perfumery. Many of the essential oils form most important medicinal agents. In the arts the cheaper oils, such as oil of turpentine, are used in the manufacture of varnishes; the reducing influence of the oil of cloves is utilized in the silvering of mirror glass; and oils of turpentine, lavender, and spike are used as vehicles for painting, more particularly for the painting of pottery and glass.

The essentials oils are subject to extensive adulteration. The presence of fatty oil is easily detected by the formation of a permanent grease spot on paper on which the suspected mixture is dropped. The admixture of fixed oil may also be demonstrated by distillation, when the volatile portion goes over, leaving the fatty oil, or by treatment of the suspected sample with strong spirit, which dissolves out the essential oil, and leaves the fatty oil as a separate layer. The presence of spirit of wine in an essential oil may be readily proved by shaking up a specimen of the oil with a measured quantity of water in a graduated glass. If the oil is pure there will be little or no change in the volume of the water layer after the complete separation of the oil and water by repose; but if, on the other hand, the oil has been mixed with spirit, the water will have extracted the spirit and decreased the apparent amount of essential oil, and increased the watery layer in proportion to the extent of the falsification. In dealing with very small samples a test by sight is obviously inapplicable, and in such cases the existence of alcohol in the watery solution may be demonstrated by the molybdenum test. This consists of treating a drop or two of water separated from the oil under examination with a solution of molybdic acid in ten parts of sulphuric acid. If the water contains alcohol, a characteristic intense blue reaction at once exhibits itself. The behaviour of essential oils towards alcohol is also made the basis of a test of their purity. The test is effected by mixing the essential oil with two volumes of absolute alcohol, and thereafter observing the volume of diluted alcohol sp. gr. 0·889 required to render the clear solution opalescent. The falsification of a costly essential oil with one of inferior value is a fraud which can only be detected with much difficulty. In practice a fair estimate of the purity of an essential oil and of its individual character may be made by some experience of its smell as rubbed on the hands; colour, boiling point, specific gravity, and other physical properties may also be usefully observed in aiding to form an estimate of the genuineness and value of a sample. Colour tests with various reagents are also used for the identification of the various essential oils. Among these are Fröhde's test (a solution of molybdate of sodium in sulphuric acid), sulphuric acid itself, fuming nitric acid, alcoholic solution of hydrochloric acid and picric acid, &c.

In the following list the essential oils ordinarily met with in commerce, with their sources, general applications whether in medicine, in perfumery, in the arts, or as flavouring materials, and some of their physical properties, are tabulated. The specific gravities and power of turning the plane of polarization, given for a column 10 inches long, are extracted from Dr Gladstone's paper

on Essential Oils (*Jour. Chem. Soc.*, new ser., vol. ii., 1864). Such of the oils as are of sufficient importance are separately noticed in their proper places.

Name of Oil.	Source.	Sp. gr.	Rotation for a column 10 inches long.	Principal Application.
Aniseed	*Pimpinella anisitum*	0·9552	− 1°	Med., flavouring
Australian sassafras	*Atherosperma moschata*	1·0425	+ 7°	Medicine.
Bay	*Laurus nobilis*	·8808	− 6°	Med.
Bergamot	*Citrus Bergamia*	·8825	+ 23°	Med., perf., flav.
Birch-bark	*Betula alba*	·9005	+ 38°	....
Bitter almonds	*Amygdalus communis*, var. *amara*	..	..	Med., flav.
Buchu leaves	*Barosma* species	..	..	Med.
Cajeput	*Melaleuca Cajuputi*	·9203	0°	Med.
Calamus	*Acorus Calamus*	·9388	+ 43°·5	....
Caraway	*Carum Carui*	·8945	+ 63°	Med., flav.
Cardamoms	*Amomum* species	..	..	Med., flav.
Cascarilla	*Croton Eluteria*	·8956	+ 26°	....
Cassia	*Cinnamomum Cassia*	1·0297	0°	Med., perf., flav.
Cedar	*Juniperus virginiana*	·9622	+ 3°	Perf.
Cedrat	*Citrus medica*	·8584	+156°	Perf.
Chamomile	*Matricaria Chamomilla*	..	..	Med.
Citronella	*Andropogon Nardus*	·8908	− 4°	Perf.
Cloves	*Caryophyllus aromaticus*	1·0475	− 4°	Med., perf., flav., arts.
Copaiba	*Copaifera officinalis*	·878	..	Med.
Coriander	*Coriandrum sativum*	·8775	+ 21°?	Med., flav.

Orange-peel (Florence)	....	·8864	+216°	....
Parsley	*Apium Petroselinum*	·9926	− 9°	Flav.
Patchouli	*Pogostemon Patchouli*	·9554	..	Perf.
Pennyroyal	*Mentha Pulegium*	..	..	Med.
Peppermint	*Mentha Piperita*	·9028	− 72°	Med., perf., flav.
Petitgrain	*Citrus vulgaris*	·8765	+ 26°	Perf.
Pimento	*Eugenia Pimenta*	1·037	..	Med., flav.
Rose	*Rosa damascena*	·8912	− 7°	Med., perf., flav.
Rosemary	*Rosmarinus officinalis*	·9080	+ 17°	Med., perf.
Rosewood	*Convolvulus scoparius*	·9064	− 16°	Perf.
Rue	*Ruta graveolens*	..	..	Med.
Sage	*Salvia officinalis*	..	..	Med., flav.
Sandalwood	*Santalum album*	·9750	− 50°	Med., perf.
Sassafras	*Sassafras officinalis*	1·090	..	Med., perf., flav.
Savin	*Juniperus Sabina*	..	..	Med.
Spearmint	*Mentha viridis*	·914	..	Med., perf., flav.
Spike	*Lavandula Spica*	..	..	Med., arts.
Star anise	*Illicium anisatum*	..	..	Med., flav.
Thyme	*Thymus vulgaris*	·8843	..	Med., perf.
Turpentine	*Pinus* species	·8727	− 79°	Med., arts.
Valerian	*Valeriana officinalis*	.	..	Med.
Verbena	*Aloysia citriodora*	·8812	− 6°	Perf.
Vetivert	*Andropogon muricatus*	1·007	..	Perf.
Wintergreen	*Gaultheria procumbens*	1·1423	+ 3°	Med.
Wormwood	*Artemisia Absinthium*	·9122	..	Med., flav.

Apart from the oil of turpentine, commerce in essential oils is limited as regards bulk, although the value of the various articles is considerable. The cultivation of plants for their odoriferous principles and the extraction of essential oils are characteristic industries of Grasse, Nice, and Cannes, in the south of France. About Mitcham in Surrey, and in Herefordshire and Bedfordshire, several plants, principally lavender and other labiates, are largely cultivated as sources of essential oils; but the localities whence the greater bulk of oils are drawn are widespread and as numerous as are the materials themselves. (J. PA.)

OISE, a department of northern France, three-fourths of which belonged to Île-de-France, and the rest to Picardy, is situated between 49° 4′ and 49° 46′ N. lat. and 1° 40′ and 3° 10′ E. long., and is bounded on the N. by Somme, on the E. by Aisne, on the S. by Seine-et-Marne and Seine-et-Oise, and on the W. by Eure and Seine-Inférieure. Its greatest length is 75 miles from north-west to south-east, whilst its breadth from north to south varies from 30 to 44 miles. The department is a moderately elevated plateau with pleasant valleys and fine forests, such as those of Compiègne, Ermenonville, Chantilly, and Hallatte, all in the south. It belongs almost entirely to the basin of the Seine,—the Somme and the Bresle, which flow into the English Channel, draining but a small area. The most important river is the Oise, which flows through a broad and fertile valley from north-east to south-west, past the towns of Noyon, Compiègne, Pont St Maxence, and Creil. On its right it receives the Brèche and the Thérain, and on its left the Aisne, which brings down a larger volume of water than the Oise itself, the Authonne, remarkable for the clearness and copiousness of the springs from which it rises, and the Nonette, which irrigates the valley of Senlis and Chantilly. The Ourcq, a tributary of the Marne, in the south-east, and the Epte, a tributary of the Seine, in the west, also in part belong to the department. These streams are separated by ranges of slight elevation or by isolated hills, the highest point (770 feet) being in the ridge of Bray, which stretches from Dieppe to Precy-sur-Oise. The lowest point is at the mouth of the Oise, only 66 feet above sea-level. Although the rainfall is under the average of France, several of the valleys are, owing to their nearness to the sea and the large extent of forests, moist and marshy. The climate is very variable, but the range of temperature is moderate. The population was 404,555 in 1881.

The area of Oise is 2260 square miles, of which four-fifths are arable, one-sixth woods, and one-twentieth pasture-lands. There are 54,000 horses, 5000 asses or mules, 111,000 head of cattle, 517,000 sheep (yielding in 1878 3,700,000 lb of wool), 44,000 pigs, 7000 goats, and 29,000 beehives. In 1882 the produce amounted to 911,335 quarters of wheat, 123,460 of rye, 1,031,700 of oats, with large quantities of beetroot, potatoes, and fodder, besides barley, meslin, buckwheat, colza, hemp, flax, &c. Vegetables, fruits, and milk are supplied to Paris; and wine and cider (6,646,919 gallons in 1882) are made, the latter being the drink principally consumed in the department. Industrial pursuits engage more than 160,000 of the population. A number are employed in quarrying building stone, in digging potter's clay and sand for glass-making, and in cutting turf. There are 697 steam and several hydraulic mills. The forges of Montataire near Creil employ 2000 workmen; but agricultural implements, metal utensils, optical glasses, paper, pasteboard, and various kinds of toys and small wares in bone, horn, mother-of-pearl, and ivory are made in the small workshops which are common everywhere. Chantilly employs 2000 women in making the lace for which it is famous. Beauvais, the chief town, besides its clock-making industry, has a national carpet factory, which rivals that of Gobelins at Paris. There are in the department forty-five woollen-mills with 54,000 spindles, and nine cotton-mills with 28,000; and the making of canvas, woollen fabrics, blankets, hosiery, boots and shoes, revolvers, &c., is also carried on, as well as boatbuilding. Sugar is extensively made from beetroot, and the manufactures of pottery, porcelain, and glass are also considerable. Commerce is greatly facilitated by the Oise and the Aisne, and by the lateral canal of the former. There are more than 400 miles of railway; and the roads are numerous and good. Oise contains four arrondissements—Beauvais, Clermont, Compiègne, Senlis—37 cantons, and 701 communes. It constitutes the diocese of Beauvais. The principal towns are Beauvais (population 17,516), Compiègne (13,567), Senlis (6870), Clermont (5625), Noyon (5780), Creil (7099), an important railway centre, with earthenware manufactures, and Montataire (5395).

OKEN, LORENZ (1779-1851). Under this name the great naturalist of the transcendental or deductive school is commonly known; but his real name was Lorenz Ockenfuss, under which he was baptized at Bohlsbach, Baden, being born in that small Swabian village on the 1st of August 1779. As Ockenfuss he was entered at the natural history and medical classes in the university of Würzburg, whence he proceeded to that of Göttingen,

where he became a privat-docent, and abridged his name to Oken. As Lorenz Oken he published in 1802 his small work entitled *Grundriss der Naturphilosophie, der Theorie der Sinne, und der darauf gegründeten Classification der Thiere*, the first of the series of works which placed him at the head of the "natur-philosophic" or physio-philosophical school of Germany. In it he extended to physical science the philosophical principles which Kant had applied to mental and moral science. Oken had, however, in this application been preceded by Fichte, who, acknowledging that the materials for a universal science had been discovered by Kant, declared that nothing more was needed than a systematic co-ordination of these materials; and this task Fichte undertook in his famous *Doctrine of Science* (Wissenschaftslehre), the aim of which was to construct *a priori* all knowledge. In this attempt, however, Fichte did little more than indicate the path; it was reserved for Schelling fairly to enter upon it, and for Oken, following him, to explore its mazes yet farther, and to produce a systematic plan of the country so surveyed.

In the *Grundriss der Naturphilosophie* of 1802 Oken sketched the outlines of the scheme he afterwards devoted himself to perfect. The position he advanced in that remarkable work, and to which he ever after professed adherence, is this,—"that the animal classes are virtually nothing else than a representation of the sense-organs, and that they must be arranged in accordance with them." Agreeably with this idea, Oken contends that there are only five animal classes:—(1) the *Dermatozoa*, or Invertebrates; (2) the *Glossozoa*, or Fishes, as being those animals in which a true tongue makes, for the first time, its appearance; (3) the *Rhinozoa*, or Reptiles, wherein the nose opens for the first time into the mouth and inhales air; (4) the *Otozoa*, or Birds, in which the ear for the first time opens externally; and (5) the *Ophthalmozoa*, or Mammals, in which all the organs of sense are present and complete, the eyes being movable and covered with two lids.

In 1805 Oken made another characteristic advance in the application of the *a priori* principle, by a book on generation (*Die Zeugung*, Frankfort), wherein he maintained the proposition that "all organic beings originate from and consist of *vesicles* or *cells*. These vesicles, when singly detached and regarded in their original process of production, are the infusorial mass or protoplasma (*urschleim*) whence all larger organisms fashion themselves or are evolved. Their production is therefore nothing else than a regular agglomeration of *Infusoria*,—not, of course, of species already elaborated or perfect, but of mucous vesicles or points in general, which first form themselves by their union or combination into particular species." This doctrine is strikingly analogous to the generalized results of the ablest microscopical observations on the development of animal and vegetable tissues which have been prosecuted of late years.

One year after the production of this remarkable treatise, Oken advanced another step in the development of his system, and in a volume published in 1806, in which Kieser assisted him, entitled *Beiträge zur vergleichenden Zoologie, Anatomie, und Physiologie*, he demonstrated that the intestines originate from the umbilical vesicle, and that this corresponds to the vitellus or yolk-bag. Caspar Friedrich Wolff had previously proved this fact in the chick (*Theoria Generationis*, 1774), but he did not see its application as evidence of a general law. Oken showed the importance of the discovery as an illustration of his system. In the same work Oken described and recalled attention to the *corpora Wolffiana*, or "primordial kidneys," as they are now termed and recognized.

The reputation of the young privat-docent of Göttingen had meanwhile reached the ear of Goethe, and in 1807 Oken was invited to fill the office of professor extraordinarius of the medical sciences in the university of Jena. He accepted the call, and selected for the subject of his inaugural discourse his ideas on the "Signification of the Bones of the Skull," based upon a discovery he had made in the previous year. This famous lecture was delivered in the presence of Goethe, as privy-councillor and rector of the university, and was published in the same year, with the title, *Ueber die Bedeutung der Schädelknochen*.

With regard to the origin of the idea, Oken narrates in his *Isis* that, walking one autumn day in 1806 in the Harz forest, he stumbled upon the blanched skull of a deer, picked up the partially dislocated bones, and contemplated them for a while, when the truth flashed across his mind, and he exclaimed, "It is a vertebral column!" At a meeting of the German naturalists held at Jena some years afterwards Professor Kieser gave an account of Oken's discovery in the presence of the grand-duke, which account is printed in the *Tageblatt*, or "proceedings," of that meeting. The professor states that Oken communicated to him his discovery when journeying in 1806 to the island of Wangeroog. On their return to Göttingen Oken explained his ideas by reference to the skull of a turtle in Kieser's collection, which he disarticulated for that purpose with his own hands. "It is with the greatest pleasure," writes Kieser, "that I am able to show here the same skull, after having it thirty years in my collection. The single bones of the skull are marked by Oken's own handwriting, which may be so easily known." There was a cause, as we shall presently see, for this circumstantial testimony.

Oken, having delivered and printed his introductory lecture in 1807, informs us (*Isis*, No. 7) that he presented copies to Goethe and to other members of the grand-duke's Government. "Goethe was so pleased with my discovery as to invite me to stay with him during the Easter week of 1808 in his house at Weimar, which invitation I accepted."

The range of Oken's lectures at Jena was a wide one, and they were highly esteemed. They embraced the subjects of natural philosophy, general natural history, zoology, comparative anatomy, the physiology of man, of animals, and of plants. The spirit with which he grappled with the vast scope of science is characteristically illustrated in his essay *Ueber das Universum als Fortsetzung des Sinnensystems*, 1808. In this work he lays it down that "organism is none other than a combination of all the universe's activities within a single individual body." This doctrine led him to the conviction that "world and organism are one in kind, and do not stand merely in harmony with each other."

In the same year he published his *Erste Ideen zur Theorie des Lichts*, &c., in which he advanced the proposition that "light could be nothing but a polar tension of the ether, evoked by a central body in antagonism with the planets, and heat was none other than a motion of this ether,"—a sort of vague anticipation of the doctrine of the "correlation of physical forces."

In 1809 Oken extended his system to the mineral world, arranging the ores, not according to the metals, but agreeably to their combinations with oxygen, acids, and sulphur. In 1810 he summed up his views on organic and inorganic natures into one compendious system. The first edition of the *Lehrbuch der Naturphilosophie* appeared in that and the following years, in which he sought to bring his different doctrines into mutual connexion, and to "show that the mineral, vegetable, and animal kingdoms are not to be arranged arbitrarily in accordance with single and isolated characters, but to be based upon the cardinal organs or anatomical systems, from which a firmly established number of classes would necessarily be evolved; that each class,

moreover, takes its starting-point from below, and consequently that all of them pass parallel to each other;" and that, "as in chemistry, where the combinations follow a definite numerical law, so also in anatomy the organs, in physiology the functions, and in natural history the classes, families, and even genera of minerals, plants, and animals present a similar arithmetical ratio."

The *Lehrbuch* procured for Oken the title of Hofrath, or court-councillor. In 1812 he was appointed ordinary professor of the natural sciences.

In 1816 he commenced the publication of his well-known periodical, entitled *Isis, eine encyclopädische Zeitschrift, vorzüglich für Naturgeschichte, vergleichende Anatomie, und Physiologie*. In this journal appeared essays and notices not only on the natural sciences but on other subjects of interest; poetry, and even comments on the politics of other German states, were occasionally admitted. This led to representations and remonstrances from the Governments criticized or impugned, and the court of Weimar called upon Oken either to suppress the *Isis* or resign his professorship. He chose the latter alternative. The publication of the *Isis* at Weimar was prohibited. Oken made arrangements for its issue at Rudolstadt, and this continued uninterruptedly until the year 1848.

The independent spirit manifested by Oken excited his courtly enemies to harsher measures. An accusation was preferred against him as a member of a forbidden "secret democratic society"; he stood his trial and was acquitted. He thereupon retired for a while into private life, occupying himself with the editorship of the *Isis* and with a series of natural-history manuals in which he considered that he had arranged for the first time the genera and species in accordance with the only true or physio-philosophical principles, stating briefly everything of vital importance respecting them, and maintaining that it was the first attempt to frame a truly scientific history of nature.

In 1821 Oken promulgated in his *Isis* the first idea of the annual general meetings of the German naturalists and medical practitioners, which happy idea was realized in the following year, when the first meeting was held at Leipsic. They have been continued ever since in Germany; and similar annual scientific gatherings have been originated in other countries. The British Association for the Advancement of Science was at the outset avowedly organized after the German or Okenian model.

In 1828 Oken resumed his original humble duties as privat-docent in the newly-established university of Munich, and soon afterwards he was appointed ordinary professor in the same university. In 1832, on the proposal by the Bavarian Government to transfer him to a professorship in a provincial university of the state, he resigned his appointments and left the kingdom.

Switzerland has the honour of affording the final place of refuge, with means of an independent pursuit of science, to this philosophic and patriotic naturalist. Oken was appointed in 1833 to the professorship of natural history in the then recently-established university of Zurich. There he continued to reside, fulfilling his professional duties and promoting the progress of his favourite sciences, until his death in the seventy-second year of his age (11th August 1851).

All Oken's writings are eminently deductive illustrations of a foregone and assumed principle, which, with other philosophers of the transcendental school, he deemed equal to the explanation of all the mysteries of nature. According to him, the head was a repetition of the trunk—a kind of second trunk, with its limbs and other appendages; this sum of his observations and comparisons—few of which he ever gave in detail—ought always to be borne in mind in comparing the share taken by Oken in homological anatomy with the progress made by other cultivators of that philosophical branch of the science.

The idea of the analogy between the skull, or parts of the skull, and the vertebral column had been previously propounded and ventilated in their lectures by Autenreith and Kielmeyer, and in the writings of J. P. Frank. By Oken it was applied chiefly in illustration of the mystical system of Schelling—the "all-in-all" and "all-in-every-part." From the earliest to the latest of Oken's writings on the subject, "the head is a repetition of the whole trunk with all its systems: the brain is the spinal cord; the cranium is the vertebral column; the mouth is intestine and abdomen; the nose is the lungs and thorax; the jaws are the limbs; and the teeth the claws or nails." Spix, in his folio *Cephalogenesis* (1818), richly illustrated comparative craniology, but presented the facts under the same transcendental guise; and Cuvier ably availed himself of the extravagances of these disciples of Schelling to cast ridicule on the whole inquiry into those higher relations of parts to the archetype which Professor Owen has called "general homologies."

The vertebral theory of the skull had practically disappeared from anatomical science when the labours of Cuvier drew to their close. In Owen's *Archetype and Homologies of the Vertebrate Skeleton* the idea was not only revived but worked out for the first time inductively, and the theory rightly stated, as follows:—"The head is not a virtual equivalent of the trunk, but is only a portion, *i.e.*, certain modified segments, of the whole body. The jaws are the 'hæmal arches' of the first two segments; they are not limbs of the head" (p. 176).

Vaguely and strangely, however, as Oken had blended the idea with his *a priori* conception of the nature of the head, the chance of appropriating it seems to have overcome the moral sense of Goethe,—unless indeed the poet deceived himself. Comparative osteology had early attracted Goethe's attention. In 1786 he published at Jena his essay *Ueber den Zwischenkieferknochen des Menschen und der Thiere*, showing that the intermaxillary bone existed in man as well as in brutes. But not a word in this essay gives the remotest hint of his having then possessed the idea of the vertebral analogies of the skull. In 1820, in his *Morphologie*, he first publicly stated that thirty years before the date of that publication he had discovered the secret relationship between the vertebræ and the bones of the head, and that he had always continued to meditate on this subject. The circumstances under which the poet, in 1820, narrates having become inspired with the original idea are suspiciously analogous to those described by Oken in 1807, as producing the same effect on his mind. A bleached skull is accidentally discovered in both instances: in Oken's it was that of a deer in the Harz forest; in Goethe's it was that of a sheep picked up on the shores of the Lido, at Venice.

It may be assumed that Oken, when a privat-docent at Gottingen in 1806, knew nothing of this unpublished idea or discovery of Goethe, and that Goethe first became aware that Oken had the idea of the vertebral relations of the skull when he listened to the introductory discourse in which the young professor, invited by the poet to Jena, selected this very idea for its subject. It is incredible that Oken, had he adopted the idea from Goethe, or been aware of an anticipation by him, should have omitted to acknowledge the source—should not rather have eagerly embraced so appropriate an opportunity of doing graceful homage to the originality and genius of his patron.

The anatomist having lectured for an hour plainly unconscious of any such anticipation, it seems hardly less incredible that the poet should not have mentioned to the young lecturer his previous conception of the vertebro-cranial theory, and the singular coincidence of the accidental circumstance which he subsequently alleged to have produced that discovery. On the contrary, Goethe permits Oken to publish his famous lecture, with the same unconsciousness of any anticipation as when he delivered it; and Oken, in the same state of belief, transmits a copy to Goethe, who thereupon honours the professor with special marks of attention and an invitation to his house. No hint of any claim of the host is given to the guest; no word of reclamation in any shape appears for some years. In Goethe's *Tages- und Jahres-Hefte*, he refers to two friends, Reimer and Voigt, as being cognizant in 1807 of his theory. Why did not one or other of these make known to Oken that he had been so anticipated? "I told my friends to keep quiet," writes Goethe in 1825! Spix, in the meanwhile, in 1815, contributes his share to the development of Oken's idea in his *Cephalogenesis*; Ulrich follows in 1816 with his *Schildkrötenschädel*; next appears the contribution, in 1818, by Bojanus, to the vertebral theory of the skull, amplified in the *Paragon* to that anatomist's admirable *Anatome Testudinis Europææ* (1821). And now for the first time, in 1818, Bojanus, visiting some friends at Weimar, there hears the rumour that his friend Oken had been anticipated by the great poet. He communicates it to Oken, who, like an honest man, at once published the statement made by Goethe's friends in the *Isis* of that year, offering no reflexion on the poet, but restricting himself to a detailed and interesting account of the circumstances under which he himself had been led independently to make his discovery, when wandering in 1806 through the Harz. It was enough for him thus to vindicate his own claims: he abstains from any comment reflecting on Goethe, and maintained the same blame-

less silence when Goethe ventured for the first time to claim for himself, in 1820, the merit of having entertained the same idea, or made the discovery, thirty years previously.

The German naturalists held their annual meeting at Jena in 1836, and there Kieser publicly bore testimony, from personal knowledge, to the circumstances and dates of Oken's discovery. However, in the edition of Hegel's works by Michelet, Berlin, 1842, there appeared the following paragraph:—"The type-bone is the dorsal vertebra, provided inwards with a hole and outwards with processes, every bone being only a modification of it. This idea originated with Goethe, who worked it out in a treatise written in 1785, and published it in his *Morphologie*, 1820, p. 162. *Oken, to whom the treatise was communicated, has pretended that the idea was his own property, and has reaped the honour of it.*" This accusation again called out Oken, who thoroughly refuted it in an able, circumstantial, and temperate statement, in part vii. of the *Isis*, 1847. Goethe's osteological essay of 1785, the only one he printed in that century, is on a different subject. In the *Morphologie* of 1820-24 Goethe distinctly declares that he had never published his ideas on the vertebral theory of the skull. He could not, therefore, have sent any such essay to Oken before the year 1807. Oken, in reference to his previous endurance of Goethe's pretensions, states that, "being well aware that his fellow-labourers in natural science thoroughly appreciated the true state of the case, he confided in quiet silence in their judgment. Meckel, Spix, Ulrich, Bojanus, Carus, Cuvier, Geoffroy St Hilaire, Albers, Straus-Durckheim, Owen, Kieser, and Lichtenstein had recorded their judgment in his favour and against Goethe. But upon the appearance of the new assault in Michelet's edition of Hegel he could no longer remain silent."

Oken's bold axiom that heat is but a mode of motion of light, and the idea broached in his essay on generation (1805) that "all the parts of higher animals are made up of an aggregate of *Infusoria* or animated globular monads," are both of the same order as his proposition of the head being a repetition of the trunk, with its vertebræ and limbs Science would have profited no more from the one idea without the subsequent experimental discoveries of Oersted and Faraday, or from the other without the microscopical observations of Brown, Schleiden, and Schwann, than from the third notion without the inductive demonstration of the segmental constitution of the skull by Owen. It is questionable, indeed, whether in either case the discoverers of the true theories were excited to their labours, or in any way influenced, by the *a priori* guesses of Oken; more probable is it that the requisite researches and genuine deductions therefrom were the results of the correlated fitness of the stage of the science and the gifts of its true cultivators at such particular stage.

Oken's real claims to the support and gratitude of naturalists rest on his appreciation of the true relations of natural history to intellectual progress, of its superior teachings to the mere utilitarian applications of observed facts, of its intrinsic dignity as a science.

The following is a list of Oken's principal works:—*Grundriss der Naturphilosophie, der Theorie der Sinne, und der darauf gegründeten Classification der Thiere* (1802); *Die Zeugung* (1805); *Abriss der Biologie* (1805); *Beitrage zur vergleichenden Zoologie, Anatomie, und Physiologie* (along with Kieser, 1806-7); *Ueber die Bedeutung der Schadelknochen* (1807); *Ueber das Universum als Fortsetzung des Sinnensystems* (1808); *Erste Ideen zur Theorie des Lichts, der Finsterniss, der Farben, und der Wurme* (1808); *Grundzeichnung des natürlichen Systems der Erze* (1809); *Ueber den Werth der Naturgeschichte* (1809); *Lehrbuch der Naturphilosophie* (1809-11, 2d ed. 1831, 3d ed. 1843; Eng. tr., *Elements of Physiophilosophy*, 1847); *Lehrbuch der Naturgeschichte* (1813, 1815, 1825); *Handbuch der Naturgeschichte zum Gebrauch bei Vorlesungen* (1816-20); *Naturgeschichte fur Schulen* (1821); *Esquisse d'un Système d'Anatomie, de Physiologie, et d'Histoire Naturelle* (1812); *Allgemeine Naturgeschichte* (1833-42, 14 vols.). He also contributed a large number of papers to the *Isis* and other journals. (R. O.)

OKHOTSK. See MARITIME PROVINCE, vol. xv. p. 548.

ÖLAND, or OELAND, next to Gottland, the largest of the islands belonging to Sweden, stretches for 85 miles along the east coast of the southern extremity of that country, from which it is separated by the Calmar Sound, about 5 miles broad at the narrowest point, and not more than 10 fathoms deep in the central portion. Its greatest breadth does not exceed 8 or 9 miles, and its area is estimated at 510 square miles. Consisting for the most part of Silurian limestone, and thus forming a striking contrast to the mainland with its granite and gneiss, Öland is further remarkable on account of the peculiarities of its structure. Down the west side for a considerable distance runs a limestone ridge, rising usually in terraces, but at times in steep cliffs, to an extreme height of 200 feet; and along the east side there is a parallel ridge of sand (resting on limestone), never exceeding 90 feet. These ridges, known as the Western and Eastern Landtborgar, are connected towards the north and the south by belts of sand and heath; and the hollow between them is occupied by a desolate and almost barren tract: the southern portion or Allvar (forming fully half of the southern part of the island) presents a surface of bare red limestone scored by superficial cracks and unfathomed fissures, and calcined by the heat refracted from the surrounding heights; and the northern portion is covered at best with a copse of hazel bushes. Outside the ridges, however, Öland has quite a different aspect,—the hillsides being not unfrequently adorned with clumps of trees, and the narrow strip of alluvial coast-land with its cornfields and villages and church towers presenting an appearance of fruitfulness and prosperity. There are only a few small streams in the island; and only one lake, Hornsjö, about 3 miles long, deserves to be mentioned. Of the fir woods which once clothed a considerable area in the north the Böda crown-park is the only remnant. Grain, sandstone, and alum are exported from the island,—the alum mines at South (Södra) Mockleby being in fact the most extensive in Sweden, and furnishing 7000 tons per annum. The only town is Borgholm, on the west coast, with one of the finest castle-ruins in Sweden. The town was founded only in 1817, and has not more than 800 or 900 inhabitants; but the castle, dating at least from the 13th century, was long one of the strongest fortresses and afterwards one of the most stately palaces in the country. The island, which bears the title of a countship, was joined in 1824 to the province of Calmar. Its inhabitants, formerly styled Öningar, and showing considerable diversity of origin in the matter of speech, local customs, and physical appearance, numbered 22,820 in 1805, 37,270 in 1865, and 37,975 in 1874.

From the raid of Ragnar Lodbrok's sons in 775 Öland is frequently mentioned in Scandinavian history, and especially as a battle-ground in the wars between Denmark and the northern kingdoms. In the Middle Ages it formed a separate legislative and administrative unity. See Linne, *Ölandska och Gothlandska Resa* (1741); Marryat, *One Year in Sweden* (Lond., 1862); Andersson, *Botaniska Resa genom Öland* (1865).

OLAUS MAGNUS or MAGNI (Magnus, *i.e.*, Store, being the family name, and not a personal epithet) was born in 1490 and died at Rome in 1558. Like his elder brother, Johannes Magnus, he obtained several ecclesiastical preferments (a canonry at Upsala and at Linköping), and was employed on various diplomatic services; but on the success of the Reformation in Sweden his attachment to the old church led him to accompany his brother into exile. Settling at Rome, he ultimately became his brother's successor in the titular archbishopric of Upsala. Olaus Magnus is best remembered as the author of *Historia de Gentibus Septentrionalibus* (Rome, 1555), a work which long remained for the rest of Europe the chief authority on Swedish matters and is still a valuable repertory of much curious information in regard to Scandinavian customs and folk-lore.

OLBERS, HEINRICH WILHELM MATTHIAS (1758-1840), a distinguished astronomer, was born 11th October 1758 at Arbergen, a village near Bremen, where his father was minister. He studied medicine at Göttingen, 1777-80, attending at the same time Kaestner's mathematical course; and in 1779, while watching by the sick-bed of a fellow-student, he devised a method of calculating cometary orbits which made an epoch in the treatment of the subject, and is still extensively used (see COMET, vol. vi. p. 182). The treatise containing this important invention was made public by Baron von Zach under the title *Ueber die leichteste und bequemste Methode die Bahn eines Cometen zu berechnen* (Weimar, 1797). A table of eighty-seven calculated orbits was appended, enlarged by Encke in the second edition (1847) to 178, and by Galle in the third (1864) to 242. Olbers settled as a physician in Bremen towards the end of 1781, and practised actively for above forty years, finally retiring 1st January 1823. The greater

part of each night (he never slept more than four hours) was meantime devoted to astronomy, the upper portion of his house being fitted up as an observatory. He paid special attention to comets, and that of 1815 (period seventy-four years) bears his name in commemoration of its detection by him. He also took a leading part in the discovery of the minor planets, re-identified Ceres on the anniversary of its discovery by Piazzi, 1st January 1802, and detected Pallas on the 28th of March following. His bold hypothesis of their origin by the disruption of a primitive large planet (*Monatliche Correspondenz*, vol. vi. p. 88), although now discarded, received strong confirmation from the finding of Juno by Harding, 2d September 1804, and of Vesta by himself, 29th March 1807, in the precise regions of Cetus and Virgo where the nodes of such supposed planetary fragments should be situated. Olbers was deputed by his fellow-citizens to assist at the baptism of the king of Rome, 9th June 1811, and he was a member of the corps lègislatif in Paris 1812-13. After some years of suffering from asthma, he died 2d March 1840, at the age of eighty-one. He was twice married, and one son survived him.

Notices of his life and works will be found in *Biographische Skizzen verstorbener Bremischer Aerzte*, by Dr G. Barkhusen (Bremen, 1844); *Allgemeine geographische Ephemeriden*, vol. iv. p. 283, 1799; *Nouvelle Biographie Générale*; *Abstracts Phil. Trans.*, vol. iv. p. 268, 1843; *Astronomische Nachrichter*, vol. xxii. p. 265, also appended to A. Erman's *Briefwechsel zwischen Olbers und Bessel* (2 vols. Leipsic, 1852). A list of Olbers's extremely interesting contributions to scientific periodicals is given at p. xxxv. of the 3d ed. of his *Leichteste Methode*, and his unique collection of works relating to comets now forms part of the Pulkowa library.

OLBIA, OLBIOPOLIS, or BORYSTHENIS, in the south of Russia, on the right bank of the Borysthenes, near its month, was a colony of Miletus, 655 B.C. It was the great station for the trade with the interior, and a wealthy city from a very early time. Inscriptions, published in the *Corpus Inscr. Græc.*, vol. ii., especially the famous decree in honour of Protogenes, throw much light on its internal history in the few centuries before and after the Christian era. They show it as a Greek city, maintaining its independence with difficulty against the barbarians who continually threatened it; but the Greek life and the Greek names gradually gave place to Scythian, the city was finally merged in the surrounding tribes, and its civilization and importance disappeared. It is a commonplace among archæologists to speak of the trade-route which led across country to the northern sea from Olbia, and a find of archaic Greek coins in Prussia is appealed to as a proof; but it has recently been proved that this find of coins was an imposture. Though it is probable that such trade-routes did exist at an early time, it is highly improbable that Greek traders used them. The natives brought down their goods to the Greek colonies, and the trade was there conducted, not by money, but rather by barter. The most interesting point about the religion of Olbia is the cult of Achilles Pontarches, the Ruler of the Sea, a deity who was extensively worshipped along the northern coast of the Black Sea. He was evidently a god of the native races, in whom some analogy of name or character made the Greeks recognize their hero Achilles. Hence arose the legend, known already to Pindar, that Achilles lived on an the White Isle in the Black Sea, a god surrounded by the other heroes. Olbia was destroyed by the Getæ about 70-60 B.C., but revived, and was a flourishing city when Dio Chrysostom visited it about 100 A.D.

OLDBURY, a township of Worcestershire, England, comprising the two parishes of Oldbury and Langley, is situated on the Birmingham Canal and on the London and North-Western and Great-Western Railways, 5 miles west of Birmingham and 3 east of Dudley. Coal, iron, and limestone abound in the neighbourhood, and the town possesses chemical works, railway-carriage works, iron, edgetool, nail, and steel works, maltings, corn-mills, brick and tile kilns, and a manufactory of glass shades. There are no public buildings of importance. The population of the urban sanitary district (1678 acres) in 1871 was 16,410, and in 1881 it was 18,841.

OLDCASTLE, SIR JOHN (d. 1417), who had married Johanna, heiress of the noble family of Cobham, and in her right sat in the House of Lords as Lord Cobham, was a nobleman who at once enjoyed the personal friendship of Henry IV. and was a professed follower of Wickliffe and an adherent of Lollardy. His reputation both as soldier and as statesman stood so high that he was selected by the king to command the English auxiliaries sent by Henry to assist the duke of Burgundy in 1411; and his known friendship for the poor preachers and his maintenance of the popular religious cause gained him the title of "the good Lord Cobham." On the death of the earl of Salisbury in one of the revolts against the house of Lancaster, Oldcastle became the recognized leader of the Lollards; his castle of Cowling became their headquarters; he sheltered their preachers, and openly defied the prohibitions and proclamations of the bishops. He publicly professed his faith in the principal Lollard doctrines and refused to believe what the church taught on the eucharist, penance, the power of the keys, image-worship, and pilgrimages. The house of Lancaster had secured the throne by making promises to the people and to the nobles, and had won the support of the church by promising to put down heresy. This had set the Lollards in opposition to the new dynasty, and their discontent was increased by the ecclesiastical measnres of the king. See LOLLARDS. In consequence Lollardy remained a constant source of danger during the reign of Henry IV., giving strength to more than one rebellion, and Henry V., on his accession in 1413, determined to extirpate the heresy. While Henry IV. lived Oldcastle was protected, but in the year of the king's death he was accused in convocation of heresy and of harbouring the poor preachers. Henry V. did all in his power to protect him, laboured to make him give up his opinions, but, finding him inflexible, forbade him to appear at conrt, and permitted the bishops to proceed against him. A citation was served on him. He refused to receive it. It was accordingly posted on the doors of Rochester Castle. He refused to obey it, was excommunicated, seized, and examined, when he boldly confessed his opinions, and was imprisoned in the Tower, forty days being given him to recant. He made his escape, and his freedom was the signal for a Lollard revolt. The preachers and their followers met in St Giles's fields, and only the vigilance of the king prevented a rising. The enactments against Lollardy became even more severe than formerly. Magistrates were directed to seize suspected heretics and to hand them over to the bishops for trial; and a conviction was punished by death and forfeiture of goods. Oldcastle for some years eluded the vigilance of his enemies, but in 1417 he was seized while in hiding in Wales, taken to London, and burned. His execution was peculiarly barbarous. He was suspended from a gallows by an iron chain, a fire was kindled beneath him, and he was slowly burned to death.

In Mr Wright's collection of political songs there are one or two ballads on Sir John Oldcastle, alluding in no very complimentary terms to his Lollardism. Henry's victories had raised the war-spirit of the English people, and it was thought disgraceful that a knight and a gentleman who in his earlier days had gained the reputation of being a skilful soldier should be associated with people many of whom professed to believe that all wars were sinful. This popular contempt has perhaps led to the idea ably advocated by Mr Gairdner that Shakespeare's character of Sir John Falstaff was meant to represent Sir John Oldcastle.

Compare Lechler's *Johann Wiclif*, vol. ii. ch. iii.; Gairdner and Spedding, *Studies in English History*, ch. iii.

OLD CATHOLICS, the self-assumed name of a new party in religious Christendom, which, like the Reformers of the 16th century, has for its avowed aim the restoration of the ancient standard of Christian belief and practice; but, while the Reformers took for their model the supposed doctrines and institutions of the apostolic age, the Old Catholics have agreed to accept the decrees of the first seven general councils (down to the second of Nicæa, 787 A.D.) as authoritative and binding on the church at large. Like the Reformation, Old Catholicism may be said to have had its representatives within the Roman Church long before its formal organization; but the immediate occasion of the movement arose out of the assembling of the œcumenical council at Rome in 1869 by Pope Pius IX. That pontiff had previously given indications of a tendency towards a reactionary policy which contrasted strongly with the liberal measures which characterized his earlier career. Of such indications the dogma of the Immaculate Conception (8th December 1854) and the "Syllabus" of 1864 were the most notable instances. The "Syllabus" was a formal repudiation of the chief doctrines and theories which during the preceding twenty years had been put forward by writers of various schools of thought, but representing opinions unfavourable to the teachings of Catholicism or the claims of the Papacy; and speculations which called in question the existence of a Divine Being were condemned in the same category with views inimical to the temporal power of the Roman curia. It was for the purpose of giving more emphatic recognition and sanction to the tenets of the "Syllabus" that the œcumenical council of 1869 was professedly convened, and the announcement that such a solemn expression of the convictions of the church at large was thus to be invited was hailed by the organs of the Catholic press throughout Europe with unqualified approval. Not until the council was on the eve of assembling did it become vaguely rumoured that among the doctrines which would be brought forward for its acceptance and ratification was that of the Papal Infallibility. The mere report was, however, looked upon as a matter of such grave import that Prince Hohenlohe, the chief minister of Bavaria, was induced to use the most strenuous exertions to prevail upon the Catholic powers to combine to prevent the promulgation of such a dogma, but without success.

The council which assembled at Rome (8th December 1869) was more deserving of the name of "œcumenical" than any which had ever before obeyed the behest of emperor or pope, being attended by delegates from nearly all parts of the world. It included 49 cardinals, 9 patriarchs of the Eastern communion, 4 primates, 121 archbishops, 479 bishops, and 52 abbots and other monastic dignitaries. The total number on the day of opening was 719, increased by the 15th of January to 744. As a representative body it was, however, very unequally composed, the numerous holders of Italian bishoprics (many of which are of but small extent) constituting a large majority of the entire number. A proposal to rectify this practical inequality by dividing the whole council into eight or six sections representing national elements was summarily rejected. On the other hand, the superiority of the minority in learning and reputation was obvious. It included such names as Schwarzenberg, Mathieu, Darboy, Rauscher, Simor, Ginoulhiac, MacHale, Dupanloup, Ketteler, Strossmayer, Clifford, Kenrick, Maret, and Hefele; while in the long list of those who eventually recorded their placets in favour of the new decree scarcely a name of real eminence appears. Dr Döllinger, the foremost scholar of Catholic Germany, was not among the "fathers" of the council, but his disapproval of the new dogma was notorious, as also was that of the Comte de Montalembert in France. After protracted sittings, extending over seven months, and characterized mainly by a series of discreditable manœuvres designed to break the firm phalanx of the minority, who could only record their protests and utter eloquent remonstrances, the *Constitutio* (as it was termed) was finally laid before the council, and carried with eighty-eight dissentients, while ninety-one abstained altogether from recording any vote. The supremacy of the Roman pontiff over even an œcumenical council was thus declared in terms more explicit and emphatic than had ever before been employed (Friedrich, *Documenta*, ii. 316), while the new dogma was enunciated in the following terms:—

"We teach and define . . . that the Roman pontiff, when he speaks *ex cathedra*, that is, when in discharge of his office of Pastor and Doctor of all Christians he defines, in virtue of his supreme apostolic authority, a doctrine of faith or morals to be held by the Universal Church, is endowed with the divine assistance promised to him in Blessed Peter, with that infallibility with which our divine Redeemer willed that the church should be furnished in defining doctrine of faith or morals, and, therefore, that such definitions of the Roman pontiff are irreformable of themselves and not in virtue of the consent of the church."

When the above dogma was promulgated in its entirety (18th July 1870) in the presence of 535 fathers, only two dissentient votes were recorded. The rest of the minority had decided on quitting Rome before the final event, a resolution confirmed by the oppressive heat of the weather and the threatening aspect of the political horizon. It has since been asserted on good authority that the action of the Papal party was largely influenced by the empress of France and her advisers; and it cannot be doubted that at Rome, not less than in Paris, it was ardently hoped that this bold proclamation of Ultramontanist doctrine would have been followed by the triumph of the French arms over those of Prussia.

The conduct of the different members of the opposition on their return to the isolation of their respective dioceses can only be described as a series of pitiable tergiversations. The "sacrificio dell' intelletto," as it was termed, was the plausible maxim adopted by one and all. Seventeen of the German bishops almost immediately receded from the position they had taken up at Rome and gave in their assent to the dogma, publishing at the same time a pastoral letter in which they sought to justify their change of sentiment on the ground of expediency in relation to the interests of the church (Michelis, *Der neue Fuldaer Hirtenbrief*, 1870). Their example was followed by all the other bishops of Germany as well as by those of Bavaria. Darboy and Dupanloup in France adopted a like course and took with them the entire body of the Gallican clergy. Each bishop demanded in turn the same submission from the clergy of his diocese, the alternative being suspension from pastoral functions, to be followed by deprivation of office. It may be urged as some extenuation of this general abandonment of a great principle, that those who had refused to subscribe to the dogma received but languid support, and in some cases direct discouragement, from their respective Governments. The submission of the illustrious Hefele was generally attributed to the influence exerted by the court of Würtemberg.

The universities, being less directly under the control of the church, were prepared to show a bolder front. Dr von Schulte, professor at Prague, was one of the first to publish a formal protest. A meeting of Catholic professors and distinguished scholars convened at Nuremberg (August 1870) recorded a like dissent, and resolved on the adoption of measures for bringing about the assembling of a really free council north of the Alps. The "Appel aux Evêques Catholiques" of M. Hyacinthe Loyson (better known as "Father Hyacinthe"), after referring to the overthrow of "the two despotisms," "the empire of the Napoleons and the temporal power of the popes," appealed to the Catholic

bishops throughout the world to put an end to the schism by declaring whether the recent decrees were or were not binding on the faith of the church. This appeal, on its appearance in *La Libertà* early in 1871, was suppressed by the order of the king of Italy. On the 28th of March Dr Döllinger, in a letter of some length, set forth the reasons which compelled him also to withhold his submission alike as "a Christian, a theologian, an historical student, and a citizen." The publication of this letter was shortly followed by a sentence of excommunication pronounced against Dr Döllinger and Professor Friedrich, and read to the different congregations from the pulpits of Munich. The professors of the university, on the other hand, had shortly before evinced their resolution of affording Dr Döllinger all the moral support in their power by an address (3d April 1871) in which they denounced the Vatican decrees with unsparing severity, declaring that, at the very time when the German people had "won for themselves the post of honour on the battlefield among the nations of the earth," the German bishops had stooped to the dishonouring task of "forcing consciences in the service of an unchristian tyranny, of reducing many pious and upright men to distress and want, and of persecuting those who had but stood steadfast in their allegiance to the ancient faith" (Friedberg, *Aktenstücke z. ersten Vaticanischen Concil*, p. 187). An address to the king, drawn up a few days later, received the signatures of 12,000 Catholics. The refusal of the rites of the church to one of the signataries, Dr Zenger, when on his deathbed, elicited strong expressions of disapproval; and when, shortly after, it became necessary to fill up by election six vacancies in the council of the university, the feeling of the electors was indicated by the return of candidates who were all distinguished by their avowed dissent from the new decrees. In the following September the demand for another and a free council was responded to by the assembling of such a congress at Munich. It was composed of nearly 500 delegates, convened from almost all parts of the world; but the Teutonic element was now as manifestly predominant as the Latin element had been at Rome. The proceedings were presided over by Professor von Schulte, and lasted three days. Among those who took a prominent part in the deliberations were Landammann Keller, Windscheid, Döllinger, Reinkens, Maassen (professor of the canon law at Vienna), Friedrich, and Huber. The arrangements finally agreed upon were mainly provisional; but one of the resolutions plainly declared that it was desirable if possible to effect a reunion with the Oriental Greek and Russian Churches, and also to arrive at an "understanding" with the Protestant and Episcopal communions.

In the following year lectures were delivered at Munich by various supporters of the new movement, and the learning and oratorical powers of Reinkens were displayed with marked effect. In France the adhesion of the abbé Michaud to the cause attracted considerable interest, not only from his reputation as a preacher, but also from the notable step in advance made by his declaration that, inasmuch as the adoption of the stand-point of the Tridentine canons would render reunion with the Lutheran and the Reformed Churches impossible, the wisest course would be to insist on nothing more with respect to doctrinal belief than was embodied in the canons of the first seven œcumenical councils. The approximation which took place in the same year between the Old Catholics, as they now began to be termed, and the historical little Church of Utrecht must not be left unnoticed. Dr Döllinger, in delivering his inaugural address as rector of the university of Munich, expressed his conviction that theology had received a fresh impulse and that the religious history of Europe was entering upon a new phase.

Other circumstances contributed to invest Old Catholicism with additional importance in the eyes of mere observers. It was evident that the relations between the Roman curia and the Prussian Government were becoming extremely strained. In February 1872 appeared the first measures of the Falk ministry, having for their object the control of the influence of the clergy in the schools; and when Cardinal Hohenlohe presented himself at Rome in the following May the world was startled at the refusal of Pius IX. to receive the accredited minister of the Prussian court. In the same year two humble parish priests, Renftle of Mering in Bavaria and Tangermann of Unk[illegible] in the Rhineland, set an example of independence by refusing to accept the decrees. The former, driven from his parish church, was followed by the majority of his congregation, who, in spite of every discouragement, co[illegible]tinued faithful to him; and for years after, as successiv[illegible] members were removed by death, the crosses over the[illegible] graves recorded that they had died "true to their ancient belief." Tangermann, the poet, expelled in like manne[illegible] from his parish by the archbishop of Cologne, before long found himself the minister of a much larger congregation in the episcopal city itself. These examples exercised n[illegible] little influence, and congregations of Old Catholics wer[illegible] shortly after formed at numerous towns and villages [illegible] Bavaria, Baden, Prussia, German Switzerland, and even [illegible] Austria. At Warnsdorf in Bohemia a congregation wa[illegible] collected which still represents one of the most impo[illegible] centres of the movement. In September the second con[illegible]gress was held at Cologne. It was attended by some 50[illegible] delegates or visitors from all parts of Europe, and th[illegible] English Church was represented by the bishops of Ely an[illegible] Lincoln and other distinguished members. The general scope of the proceedings was the formation of a [illegible] definite organization; and the question of reunion wit[illegible] other churches was again a prominent topic of discussion Among those present was the late Dean Stanley, and t[illegible] striking accounts which he forwarded to *The Times* of th[illegible] whole congress did much to awaken in England a mor[illegible] widely-extended interest in the movement.

In the month of May in the following year (1873) th[illegible] celebrated Falk laws were enacted, whereby the articles 1[illegible] and 18 of the Prussian constitution were modified, so [illegible] to legalize a systematic state supervision over the ed[illegible]tion of the clergy of all denominations, and also over th[illegible] appointment and dismissal of all ministers of religi[illegible]. The measure, which at the time was interpreted as [illegible] Prince Bismarck afterwards openly declared it to have bee[illegible] viz., a direct response to the Vatican decrees, inspired th[illegible] Old Catholics with a not unreasonable expectation [illegible] the moral support of the Government would hencefo[illegible] be enlisted on their side. On the 11th of August D[illegible] Reinkens, having been duly elected bishop of the ne[illegible] community, received his consecration at Rotterdam, [illegible] "missionary-bishop of Germany," at the hands of Bish[illegible] Heykamp of Deventer. The archbishop of Utrecht, [illegible] whom it would otherwise have devolved to perform [illegible] ceremony, had died somewhat suddenly a few days before and the Ultramontanists did not scruple to interpret th[illegible] event as a sign of the divine displeasure. In the me[illegible] time the extension of the movement in Switzerland ha[illegible] been proceeding rapidly, and it was resolved that Constan[illegible] should be elected as the centre for the third congress. [illegible] proceedings occupied three days (12th to 14th September) and were of an animated and interesting character, th[illegible] intelligence that the Prussian Government had resolved [illegible] recognizing the election of Bishop Reinkens contrib[illegible] not a little to inspirit those who were present. Eng[illegible] and American theologians, of widely different scho[illegible] listened to the discussions with sympathizing appre[illegible]

tion, and even bore a part. The subjects which chiefly occupied the consideration of the assembly were the institution of a synod as the legislative and executive organ of the church, and schemes of reunion with the Greek, the African, and the Protestant communions. The unanimity which prevailed was remarkable, and not less so were the indications that the breach between the Papacy and Old Catholicism had become decisive and final. On the 20th of September the election of Bishop Reinkens was formally recognized by the German Government, and on the 7th of October he took the oath of allegiance to the king.

The following year (1874) was marked by the assembling of both a synod and a conference at Bonn, and of a congress at Freiburg in the Breisgau. The acts of the synod were mainly directed to modifications of the Roman discipline and the removal of prevalent abuses. At the congress Bishop Reinkens spoke in hopeful terms of the results of his observations during a recent missionary tour throughout Germany. The conference, held on the 14th, 15th, and 16th of September, had for its special object the discussion of the early confessions as a basis of agreement, though not necessarily of fusion, between the different communions above-named. The meetings, presided over by Dr Döllinger with an ability and tact which excited general admiration, successively took into consideration the *Filioque*, the sacraments, the canon of Scripture, the episcopal succession in the English Church, the confessional, indulgences, prayers for the dead, and the eucharist. Some divergence of views inevitably disclosed itself in the course of the discussions, but the same conciliatory tone and feeling marked the close as well as the commencement of the proceedings, and by both the English and the Continental religious press the final results were hailed as eminently auspicious. As the direct results of these deliberations it has since been decided to abolish compulsory confession and fasting, to employ the vernacular in public worship, to recognize the marriage of priests as lawful, and to allow them to administer in their churches the communion in both kinds to members of the Anglican persuasion.

Since 1874 Old Catholicism has found new adherents in other lands,—in Austria, in Italy, and in Mexico; but the controversial spirit which in past history has either broken up such organizations or largely impaired their efficiency has also marred the success of this interesting movement. In Switzerland, where important conferences were successively convened (at Solothurn in 1871, at Olten in 1872, 1873, and 1874), the unanimity of the "Christian Catholics," as they preferred to call themselves, seemed at one time in danger of being shipwrecked on the question of episcopacy. It was not until 18th September 1876 that the conflict of opinions was so far composed as to allow of the consecration of Bishop Herzog by Bishop Reinkens. The reforms introduced by M. Hyacinthe Loyson in his church at Geneva have received only a partial assent from the general body. Among the more practical results of his example is to be reckoned, however, the fact that in French Switzerland nearly all the clergy, in German Switzerland about one half, are now married men. But the congregations, which in 1876 had reached the number of fifty-five, have dwindled to thirty-five. The number of children in the different schools is stated to be somewhat under 4000 (Nippold, *Handbuch der neuesten Kirchengeschichte*, ii. 466-478).

In Germany, since the year 1878, the position of the Old Catholics has been one of considerable difficulty. While their representatives have scrupulously abstained from any course of action which could tend to embarrass the Government in its political contests, the most influential organs of that Government have systematically decried the movement and have undisguisedly aimed at its complete extinction. This change of policy is mainly due to the altered relations with the papal court. The present pontiff, skilfully ignoring the original and genuine causes in which Old Catholicism took its rise, has sought to represent its leaders as actuated by revolutionary designs and aiming at the subversion of existing institutions, while the Papacy itself has been described as the chief bulwark against social democracy and nihilistic tendencies. The Prussian Government has responded by a series of concessions to the Roman Catholic clergy, while the favour once shown to the seceding party is at an end. Bishop Reinkens himself, though he still receives a salary from the state, no longer draws it under the head of expenditure for Catholic worship. In Bavaria Professor Friedrich has been constrained to transfer his services from the theological to the philosophical faculty at Munich, and the little Old Catholic congregation has been deprived of its church. Huber's valuable literary powers have been lost to the cause by his premature decease. In France the place of M. Michaud, who has been appointed professor in the university of Bern, is in some measure filled by the return of Father Hyacinthe from Geneva. Under such conditions the continued progress of the party and even its existence are obviously seriously imperilled. But, even if, like the Albigenses, the Lollards, and other similar movements to which the assumptions of the Papacy have at different times given rise, Old Catholicism should be destined to extinction, it will not the less have left on permanent record an example of loyalty to conscientious convictions the influence of which will long survive.

Authorities.—The literature of the subject is now voluminous, but the following are among the best sources of information. (*a*) As regards the proceedings at the Vatican Council and the more immediate results of the decrees: Friedberg (Dr Emil), *Sammlung der Aktenstücke zum ersten Vaticanischen Concil mit einem Grundrisse der Geschichte desselben*, 1872; Friedrich (Dr J.), *Tagebuch während des Vaticanischen Concils geführt*, 2d ed., 1873; Id., *Le Concile du Vatican*, Brussels, 1871; Id., *Gesch. des Vatikanischen Konzils*, vol. i., 1877; Frommann (Theodor), *Gesch. u. Kritik d. Vaticanischen Concils von 1869 und 1870*, Gotha, 1872; Janus, *Der Papst und das Concil*, 1869 (a reprint of articles in the *Augsburg Allgem. Zeitung*); *An Inside View of the Vatican Council* (Archbishop Kenrick's Speech, edited by L. W. Bacon), New York; *Catholic Reform*, by Father Hyacinthe, with preface by Dean Stanley, 1874; Quirinus, *Römische Briefe vom Concil*, 1870, of which an English translation has also appeared; Von Schulte (Dr J. F.), *Concilien, Päpste, und Bischöfe*, 1871. (*b*) The proceedings of the successive congresses will be best studied in the *Stenographischer Berichte*, published at Munich, Cologne, Constance, &c.; those of the congress of Constance were summarized in an English form, with other elucidatory matter, by Professor John Mayor. (*c*) For the questions involved in the consecration of Bishop Reinkens: *Rechtsgutachten über die Frage der Anerkennung des altkatholischen Bischofe Dr Reinkens in Bayern*, Munich, 1874; Friedberg (Dr Emil), *Der Staat und d. Bischofswahlen in Deutschland*, Leipsic, 1874; Von Sybel (F.), *Das altkatholische Bisthum und das Vermögen d. römisch-katholischen Kirchengesellschaften in Preussen*, Bonn, 1874. (*d*) Reinkens's own speeches and pastorals, some of which have bee translated into English, give his personal views and experiences the *Life* of Huber has been written and published by Eberhar Stirngiebl; and the persecutions to which the Old Catholic clerg have been exposed have been set forth in a pamphlet by Professc John Mayor, *Facts and Documents*, London, 1875. (*e*) An out line of the whole movement from its first commencement to th year 1875 will be found in *The New Reformation*, by "Theodorus (J. Bass Mullinger)"; and an excellent résumé of the main fact in the history of the movement in each European country, connected with other developments of liberal thought, and wit political history, is given in the second volume of Dr F. Nippold *Handbuch der neuesten Kirchengeschichte*, vol. ii., 1883. (*f*) Th recognized organ of the movement, the *Deutscher Merkur* (formerl the *Rheinischer Merkur*), is still published weekly by P. Neuss of Bonn.

(J. B. M.)

OLDENBURG, a grand-duchy of Germany, with an are of 2480 square miles, consists of three widely separate portions of territory,—(1) the duchy of Oldenburg, (2) th principality of Lübeck, and (3) the principality of Birken feld. It ranks tenth among the states of the Germa

empire and has one vote in the federal council and three members in the reichstag.

I. The duchy of Oldenburg, comprising fully four-fifths of the entire area and population, lies between 52° 29′ and 53° 44′ N. lat. and 7° 37′ and 8° 40′ E. long., and is bounded on the N. by the German Ocean and on the other three sides by Hanover, with the exception of a small strip on the east, where it is conterminous with the territory of the free city of Bremen. It forms part of the north-western German plain defined by the Weser and the Ems, and, except on the south, where the Dammergebirge attain a height of 300 feet, it is almost entirely flat, with a slight inclination towards the sea. In respect of its soil it is divided broadly into two parts,—the higher and inland-lying "Geest," consisting of sandy plains intermixed with extensive heaths and moors, and the "marsh lands" along the coast, consisting of rich but somewhat swampy alluvial soil. The latter, which compose about one-fifth of the duchy, are protected against the inroads of the sea by dykes as in Holland; and beyond these are the so-called "watten," generally covered at high tide, but at many points being gradually reclaimed. The climate is temperate and humid; the mean temperature of the coldest month at the town of Oldenburg is 26° Fahr., of the warmest 66°. Storms are numerous and somewhat violent, owing to the almost entire absence of trees; and fogs and ague are prevalent in the marsh lands. The chief rivers are the Hunte, flowing into the Weser, and the Hase and Leda draining into the Ems. The Weser itself forms the eastern boundary for 42 miles, and internal navigation is greatly facilitated by a new canal, passing through the heart of the duchy and connecting the Hunte and the Ems. On the north there are several small coast streams conducted through the dykes by sluices, the only one of importance being the Jade, which empties itself into the Jadebusen, a deep gulf affording admirable accommodation for shipping. The duchy also contains numerous small lakes, the chief of which is the Dümmer See in the south-east corner, measuring 4 miles in length by 2½ in width. About 30 per cent. of the area of the duchy is under cultivation and 17 per cent. under pasture and meadows, while the rest consists mainly of moor and heath. The forests occupy a very small proportion of the whole, but there are some very fine old oaks. In the Geest the principal crops are rye, oats, potatoes, and buckwheat, for which the heath is sometimes prepared by burning. Large tracts of moorland are, however, useful only as producing an abundant supply of turf and peat for fuel, or as affording a scanty subsistence to the flocks of small coarse-woolled Oldenburg sheep. The rich soil of the marsh lands produces good crops of wheat, oats, rye, hemp, and rape, but is especially adapted for grazing. The fat cattle and horses raised on it are highly esteemed throughout Germany, and the former are exported in large numbers to England. Bee-keeping is also much in vogue on the moors. The live stock of Oldenburg forms a great part of its wealth, and the ratio of cattle, sheep, and horses to the population is one of the highest among the German states. There are few large estates, and the ground is mostly in the hands of small farmers, who enjoy the right of fishing and shooting on their holdings. Game, however, is scarce; but the fishing is fairly productive. The mineral wealth of Oldenburg is very small, and there are no mineral springs.

The industries are comparatively insignificant, though recently somewhat stimulated by the extension of the railway system and other causes. Woollen and cotton fabrics, stockings, jute, and cigars are made at Varel, Delmenhorst, and Lohne; cork-cutting is extensively practised in some districts, and there are a few iron-foundries. Trade is relatively of more importance, chiefly owing to the proximity of Bremen. The agricultural produce of the duchy is exported to Scandinavia, Russia, England, and the United States, in return for colonial goods and manufactures. Varel, Brake, and Elsfleth are the chief commercial harbours. In 1881 the ports of the duchy owned a merchant fleet of 345 vessels of 70,000 tons, and they are entered and cleared annually by from 2000 to 2500 vessels with an aggregate burden of 125,000 tons. Shipbuilding and boat-building are carried on at the above-named seaports and on the tributaries of the Ems. Before 1866 Oldenburg was destitute of railways, but it is now traversed by various lines. The high-roads are good; in the north some of them are laid with "klinkers" like those in Holland.

II. The principality of Lübeck, formed of the old bishopric of that name, has an area of 209 square miles, and shares in the general physical characteristics of East Holstein, within which it lies. On the north-east it extends to the Baltic Sea, and on the south-west it is bounded by the Trave. The chief rivers are the Schwartau, a tributary of the Trave, and the Schwentine, flowing northwards to the Gulf of Kiel. The scenery of Lübeck is often picturesque, especially in the vicinity of the Plöner See and the Eutiner See, the most important of the small lakes with which it is dotted. Agriculture is practised here even more extensively than in the duchy of Oldenburg, about 75 per cent. of the area being cultivated. The population in 1880 was 34,973.

III. The principality of Birkenfeld, 194 square miles in extent, lies in the midst of the Prussian province of the Rhine, about 30 miles to the west of the Rhine at Worms and 150 miles to the south of the duchy of Oldenburg. It is a hilly district, intersected by the spurs of the Hochwald, which attain a height of over 2000 feet; the valleys, however, are fertile and produce wine and grain in considerable abundance. About two-fifths of the surface are covered with forests. Iron-founding, cotton-spinning, and other manufactures are carried on; but the characteristic industry (having its seat in Oberstein) is the polishing of agates, of which great numbers are found within the principality (compare ONYX). Birkenfeld is traversed from end to end, a distance of about 25 miles, by the Nahe, which rises close to its northern frontier. The population in 1880 was 38,685.

The total population of the grand-duchy of Oldenburg in 1880 was 337,478, showing an increase of 1·10 per cent. per annum since the census of 1875, and an average of 136 persons to the square mile. The bulk of the inhabitants are of the Saxon stock, but to the north and west there are numerous descendants of the ancient Frisians. The differences between the two races are still to some extent perceptible, but Low German ("Platt-deutsch") is universally spoken, except in one limited district, where a Frisian dialect has maintained itself. In general characteristics the Oldenburg peasants resemble the Dutch, and the absence of large landowners has contributed to make them sturdy and independent. Oldenburg has the credit of showing almost the lowest average of illegitimate births among the German states, amounting in 1881 to only 5 per cent. This is in significant contrast to the high rate (15 per cent.) among the semi-feudatory peasants of MECKLENBURG (*q.v.*). The population of Oldenburg is somewhat unequally distributed, some parts of the marsh lands containing over 300 persons to the square mile, while in the Geest the number occasionally sinks as low as 40. Nearly 80 per cent. of the inhabitants are returned as belonging to the "rural" population. The only town with more than 10,000 inhabitants is Oldenburg, the capital of the grand-duchy. The war-harbour of Wilhelmshaven, with 12,000 inhabitants, on the shore of the Jadebusen, was built by Prussia on a piece of land bought from Oldenburg. The chief towns of Birkenfeld and Lübeck are Birkenfeld and Eutin, with 2539 and 4574 inhabitants respectively. Oberstein in Birkenfeld has 4803; in the 12th century it was a lordship holding directly of the empire.

Oldenburg is a Protestant country, and the grand-duke is required to be a member of the Lutheran Church. Roman Catholicism, however, preponderates in the south-western provinces, which formerly belonged to the bishopric of Münster. Oldenburg Roman Catholics are under the sway of the bishop of Münster, who is represented

by an official at Vechta; and the Catholics of Birkenfeld belong to the diocese of Treves. At the census of 1880 there were in the grand-duchy 260,416 Protestants, 74,254 Roman Catholics, and 1654 Jews. The educational system of Oldenburg is on a similar footing to that of north Germany in general, though the scattered position of the farmhouses interferes to some extent with school attendance. The proportion of Oldenburg recruits in 1882 unable to read or write was only 0·27 per cent., which compares favourably with the average of 1·54 for the whole empire. There is no university in Oldenburg territory, but an ample supply of primary, secondary, and special schools.

The constitution of Oldenburg, based upon a decree of 1849, revised in 1852, is one of the most liberal in Germany. It provides for a single representative chamber, elected indirectly by universal suffrage and exercising concurrent rights of legislation and taxation with the grand-duke. The chamber, which consists of thirty-four members (twenty-six for Oldenburg and four for each of the principalities), meets at regular intervals of three years. The executive consists of three ministers, who are aided by a committee of the landtag, when that body is not in session. The local affairs of Birkenfeld and Lubeck are entrusted to provincial councils. All citizens are alike in the eye of the law, and all exemptions and privileges have been abolished. The municipal communities enjoy an unusual amount of independence.

The finances of each constituent state of the grand-duchy are managed separately, and there is also a fourth budget concerned with the joint administration. The last generally shows a sum of about £50,000 on each side, the expenditure including a matricular contribution of £33,500 to the imperial treasury. In the budget of 1882 the revenues of the duchy of Oldenburg, the principality of Lubeck, and the principality of Birkenfeld were estimated at £289,965, £40,419, and £43 864, while the estimated expenditure was in each case somewhat less. The duchy of Oldenburg has a debt of nearly £2,000 000 and Lubeck one of £2000, while Birkenfeld and the grand-duchy as a whole are free of debt. An annual allowance of about £13,000 is made to the grand-duke, and he is believed to derive as much more from his private estates. The troops of Oldenburg furnish the German army with a regiment of infantry, a regiment of cavalry, and two batteries of artillery.

History.—The earliest recorded inhabitants of this district were the Germanic Chauci, who were afterwards merged in the Frisians. Old chroniclers delight in tracing the genealogy of the counts of Oldenburg up to Wittekind, the stubborn opponent of Charlemagne; but their first historical representative is Elmar I., who flourished at the close of the 11th century. His descendants appear as vassals of the powerful Saxon dukes, but attained the rank of independent princes of the empire on the dissolution of the Saxon power by Frederick Barbarossa (c. 1180). The countship of Delmenhorst at this time formed part of the Oldenburg dominions, but was afterwards frequently separated from them, and was not lastingly united under the same ruler till the beginning of the 17th century. The northern and western parts of the present duchy of Oldenburg were in the hands of more or less independent Frisian princes, who had generally remained pagans; and Oldenburg history for the next two centuries is largely concerned with feuds with these small potentates, and gradual extension of territory at their expense. Bremen and Munster were also frequently at war with the counts of Oldenburg. In 1448 Count Christian VIII. was elected king of Denmark, and, a little later, duke of Holstein and Schleswig, the latter event pregnant with important consequences for future history. Oldenburg was made over to his brother Gerhard, an ambitious prince, whose turbulent disposition resulted in an abdication in favour of his sons, forced on him by a league of Hamburg, Lubeck, and Bremen. Protestantism was introduced by Anton I. (1531-1573), who, however, remained loyal to Charles V. in the Schmalkald war, and was thus enabled to increase his territories. On the accession of Anton Gunther in the beginning of the 17th century Oldenburg and Delmenhorst were finally welded into one, and about the same period the last free Frisian states, Jever and Kniphausen, were also absorbed by Oldenburg. Anton Gunther proved himself the wisest prince who had ruled in Oldenburg; and by his prudent neutrality in the Thirty Years' War secured for his domains immunity from the devastations to which most other German states were exposed. He also obtained from the emperor the right to levy tolls on vessels passing up the Weser, a lucrative grant, which soon formed one-fifth of his revenues. On his death without issue in 1667 the succession passed to the Danish reigning house, after the claims of the Holstein-Gottorp and Holstein-Sonderburg branches of the family had been compromised. Oldenburg remained under the sway of the Danish monarchs for about a century,—a period, on the whole, of peaceful development. At length, in 1773, the Danish monarch agreed to a family compact, in accordance with which he resigned Oldenburg to the Holstein-Gottorp line in return for a renunciation on their part of all claim to Schleswig and Holstein. The head of the Holstein-Gottorp family at this time was the grand-duke Paul of Russia (afterwards the emperor Paul I.); but he handed over Oldenburg, which was now created a duchy, to his cousin Frederick Augustus, bishop of Lubeck, representative of a younger line. The bishop's son, who followed his father in 1785, was a man of weak intellect; and his cousin, Peter Frederick Louis, who acted as administrator and eventually succeeded to the throne, is the direct progenitor of the present grand-duke. Peter had the task of managing the duchy in the troublous times of the Napoleonic wars, and, though he joined the Confederation of the Rhine, had afterwards to see his domains forcibly annexed to France on his refusal to exchange them for Erfurt. This led him to join the allies, and his services were rewarded at the congress of Vienna by the addition of Birkenfeld to his dominions, which were also raised to the rank of a grand-duchy. The secularized bishopric of Lubeck had been already added to Oldenburg in 1803. Oldenburg did not escape the revolutionary wave that swept over Europe in 1848, but no very serious disturbances took place, and the grand-duke granted a constitution in 1849. This constitution was of an ultra-liberal character, and, as the country had hitherto been ruled in the spirit of an enlightened but absolute despotism, strengthened by the absence of a privileged class of nobles, the unimportance of the towns, and the comparative independence of the peasantry, it was inevitable that it should not work at once without friction. In 1852 it had to submit to some modification, which, however, still left it one of the most liberal constitutions in Germany. In 1864 the grand-duke seemed at first inclined to insist upon his claims to the Schleswig-Holstein succession, but he ultimately resigned them in favour of Prussia. In 1866 he sided with that power against Austria, and in 1871 the grand-duchy became a member of the German empire.

See Halem, *Gesch. d. Herzogth. Oldenburg* (1794-96); Runde, *Oldenburgische Chronik* (3d ed., 1863); Böse, *Das Grossherzogthum Oldenburg* (1863); Kollmann, *Das Herzogthum Oldenburg in seiner wirthschaftlichen Entwickelung während der letzten 25 Jahre* (1879); the publications of the Statistical Bureau of Oldenburg; the annual *Hof- und Staatshandbuch des Grossherzogthums Oldenburg*.

OLDENBURG, the capital of the grand-duchy of that name, is a quiet and pleasant-looking town, situated 24 miles to the west of Bremen, on the Hunte, which is navigable for river-craft up to this point. The inner or old town, with its somewhat narrow streets, is surrounded by avenues laid out on the site of the former ramparts, beyond which are the villas, parks, and gardens of the more modern quarters. Oldenburg has almost nothing to show in the shape of interesting old buildings. The Lambertikirche, though dating from the 13th century, has been so transformed in the present century as to show no trace of its antiquity. The palaces of the grand-duke and the town-house are Renaissance buildings of the 17th and 18th centuries. Among the other prominent buildings—all modern—are the theatre, the law-courts, the gymnasium, the commercial school, the three hospitals, and the new Roman Catholic church. The grand-ducal picture-gallery in the Augusteum includes works by Veronese, Velazquez, Murillo, and Rubens; and there are collections of modern paintings and sculptures in the two palaces. The public library contains 150,000 vols., and the duke's private library has 50,000. There is also a museum with a collection of antiquities and a cabinet of natural history. The industries of Oldenburg, which are of no great importance, include iron-founding and the making of tobacco, soap, and leather. A considerable trade is carried on in grain, and the horse-fairs are largely frequented. The population in 1880 was 20,575, or, including the suburban village of Osternburg on the other side of the Hunte and the Hunte-Ems Canal, 24,678. About four-fifths of these are Protestants.

According to popular tradition Oldenburg was founded by Walbert, grandson of Wittekind, and named after his wife Altburga; but the first historical mention of it occurs in a document of 1108. It was fortified in 1155, and received a municipal charter in 1345. The subsequent history of the town is merged in that of the grand-duchy.

(J. F. M.)

OLDHAM, a municipal and parliamentary borough and important manufacturing town of south-east Lancashire, is situated on an eminence near the source of the Medlock, at the junction of several railway lines, 6 miles north-east of Manchester. By the Oldham canal it has water-communication with Manchester, Ashton, Stockport, and Rochdale. Although consisting chiefly of monotonous rows of workmen's houses, interspersed with numerous immense factories and workshops, Oldham has some good

streets and a number of imposing public buildings. Among these the principal are the town-hall, a fine structure in the Grecian style, with a tetrastyle portico copied from the Ionic temple of Ceres near Athens, enlarged by a new wing erected in 1880 at a cost of £24,000, the nucleus of much more extensive municipal buildings; the lyceum, in the Italian style, erected in 1854 and enlarged in 1880; the public baths, erected in 1854—partly by money raised for a memorial to Sir Robert Peel—and enlarged in 1880; the workmen's hall, erected in 1844 and enlarged in 1854; the Werneth mechanics' institute, 1867; the infirmary, erected in 1870 and enlarged in 1877; and the new post-office, 1877. There is a grammar school, founded in 1611; but a more important educational endowment is the blue-coat school, for which a sum of £40,000 was left in 1808. On account of a legal dispute the money was allowed to accumulate for over twenty years, so that the school started with an endowment of £100,000. The town possesses a commodious general market, opened in 1856, and also a fish market, opened in 1873. Both the gasworks and waterworks have since 1853 been in the hands of the corporation. Additional reservoirs have been added to meet the increasing needs of the town, their total capacity being now 1,233,500,000 gallons. During the cotton famine occupation was given to many of the distressed operatives in laying out 72 acres as a public park, which, under the name of the Alexandra Park, was opened in 1865, at a cost of about £37,000. The town, which is one of the most important seats of the cotton manufacture in the world, owes its prosperity in great part to its situation on the edge of the Lancashire coal-field, where the mineral is very easily wrought. There are many valuable seams of coal in the immediate neighbourhood of the town, those in highest repute being the Black Mine and Bent Mine coals. From entries in the church registers it would appear that linens were manufactured in Oldham as early as 1630. Watermills were introduced in 1770, and with the adoption of Arkwright's inventions the cotton industry spread with great rapidity. After the introduction of steam power the town, owing to its proximity to the coal-beds, soon assumed a leading place in the manufacture of cotton. The total number of persons engaged in the industry is over 30,000, the annual consumption of cotton being over 700,000 bales, or about one-fourth of the whole quantity of cotton imported into the United Kingdom. The principal manufactures are fustians, velvets, cords, hats, shirtings, sheetings, and nankeens. There are also large foundries and mill and cotton machinery works, the most extensive establishment being that of Platt and Co. The gas-meters made at Oldham have a high reputation, and there are also several large manufactories of sewing-machines. The town is divided into eight wards, and is governed by a mayor, eight aldermen, and twenty-four councillors. The area of the township is coextensive with that of the municipal borough, and comprehends 4730 acres, of which 13 are water. The parliamentary borough has an area of 12,310 acres, and, in addition to Oldham, includes the townships of Crompton, Royton, and Chadderton, and part of the parish of Ashton-under-Lyne. Within the present century the growth of Oldham has been very rapid. In 1714 the population numbered only 1750, which in 1801 had increased to 12,024, in 1841 to 42,595, in 1861 to 72,333, in 1871 to 82,633, and in 1881 to 111,343. The population of the parliamentary borough in 1871 was 113,100, and in 1881 it was 152,513.

The name Oldham is of Saxon origin. A Roman road, of which some traces are still left, passes through the township, but it does not appear to have been a Roman station. It is not mentioned in Domesday; but in the reign of Henry III. Alwardus de Aldholme is referred to as holding "two bovats of land in Vernet (Werneth)." A daughter and co-heiress of this Alwardus conveyed Werneth Hall and its manor to the Cudworths, a branch of the Yorkshire family, with whom it remained till the early part of last century. From the Oldhams was descended Hugh Oldham, who died bishop of Exeter in 1519. In 1826 the town was placed under the care of a board of commissioners, and in 1849 it received municipal government. Since 1832 it has returned two members to parliament.

OLDHAM, JOHN (1653-1683), a satirist of the Restoration period, achieved notoriety by his *Satires on the Jesuits*, published during the heat of the excitement caused by the revelations of Titus Oates and the murder of Godfrey in 1678. In such a time of national panic and hatred "who peppered the highest was surest to please," and Oldham's satires could hardly be surpassed for energy of invective and copiousness of coarse extravagant irony. They were extravagant enough to pass in a more sober age for burlesques of anti-Popish frenzy. Oldham was at the time a tutor in a judge's family. He was the son of a Nonconformist minister, born at Shipton, near Tetbury in Gloucestershire, in 1653, was a B.A. of Oxford (Edmund Hall), and had been for some three years an usher in a school at Croydon. Before he appeared as a satirist, and while he was still an usher, his verses, circulated in MS., had attracted the attention of Will's Coffee-house, and Rochester with some of his boon companions had sallied down to Croydon to see what the new poet was like. It was probably an extravagantly humorous dithyrambic drunkard's soliloquy that roused their curiosity, and when they found him a tall, thin, consumptive, harsh-featured cynic they apparently left him to his drudgery. After the success of his *Satires on the Jesuits*, Oldham wrote more satires, imitations of Horace and Juvenal, and one of them, a satire on poets, setting forth bitterly their degradation, their poverty, their humiliating adulation of patrons, is often quoted as an index to the condition of men of letters in those days. He died prematurely (1683) at the age of thirty, and was eloquently lamented by Dryden as the "Marcellus of our tongue."

> "Farewell, too little and too lately known,
> Whom I began to think and call my own;
> For sure our souls were near allied, and thine
> Cast in the same poetic mould as mine."

Oldham's verse was rugged, and his rage, as Pope said, "too like Billingsgate"; but "maturing time," as Dryden hoped, might have softened these faults. Donne and Cowley were his literary models, and he poured into their forms great warmth of feeling, wealth of incident, and commanding force of language.

OLDYS, WILLIAM (1696-1761), a useful bibliographer, was the natural son of Dr Oldys, chancellor of Lincoln, and was born in 1696. He was a good scholar, but of intemperate habits, and never succeeded in freeing himself from the thraldom of Grub Street,—unless, indeed, when he was employed for some years by Harley, earl of Oxford, as librarian. He is best known by his *British Librarian*, an esteemed but unfinished work, which began to appear in 1737 (see BIBLIOGRAPHY, vol. iii. p. 652). He was appointed Norroy king-at-arms by the duke of Norfolk. His death took place on 15th April 1761. A MS. collecti[illegible] of notes by Oldys on various bibliographical subjects and a copy of Langbaine's *Lives* copiously annotated by [illegible] are preserved in the British Museum.

OLEANDER is the common name for the shrub kn[illegible] to botanists as *Nerium Oleander*. It is a native of th[illegible] Mediterranean and Levant, and is characterized by its tal[illegible] shrubby habit and its thick lance-shaped opposite leave[illegible] which exude a milky juice when punctured. The flowe[illegible] are borne in terminal clusters, and are like those of t[illegible] common periwinkle (*Vinca*), but are of a rose colour, rare[illegible] white, and the throat or upper edge of the tube of th[illegible] corolla is occupied by outgrowths in the form of lobe[illegible]

and fringed petal-like scales. The hairy anthers adhere to the thickened stigma. The fruit or seed-vessel consists of two long pods, which, bursting along one edge, liberate a number of seeds, each of which is provided with a tuft of silky hairs like thistle down at the upper end. The genus belongs to the family of *Apocynaceæ*, a family that, as is usual where the juice has a milky appearance, is marked by its poisonous properties. Cases are recorded by Lindley of children poisoned by the flowers. The same author also narrates how in the course of the Peninsular War some French soldiers died in consequence of employing skewers made from freshly-cut twigs of oleander for roasting their meat. The oleander was known to the Greeks under three names, viz., *rhododendron*, *nerion*, and *rhododaphne*, and is well described by Pliny (xvi. 20), who mentions its rose-like flowers and poisonous qualities, at the same time stating that it was considered serviceable as a remedy against snake-bite. The modern Greeks still know the plant as ῥοδοδάφνη, although in a figure in the Rinuccini MSS. of Dioscorides a plant is represented under this name, which, however, has rather the appearance of a willow herb, *Epilobium*. The oleander has long been cultivated in greenhouses in England, being, as Gerard says, "a small shrub of a gallant shewe"; and of late numerous varieties, differing in the colour of their flowers and in the mutation of their stamens into petals so as to form double flowers, have been introduced.

Nerium Oleander.

OLEARIUS, ADAM, a German traveller whose true name was Oelschläger, was born at Aschersleben near Magdeburg in 1600, and died at Gottorp 22d February 1671. After studying at Leipsic he became librarian and court mathematician to Duke Frederick III. of Holstein-Gottorp, and in 1633 he was appointed secretary to the ambassadors Philip Crusius and Otto Brüggemann or Brugman sent by the duke to Muscovy and Persia in the hope of making arrangements by which his newly-founded city of Frederikstad should become the terminus of an overland silk-trade. It is by his admirable narrative of this legation (*Beschreibung der moskowitischen und persischen Reise*, Schleswig, 1647, and afterwards in several enlarged editions) that Olearius is best known, though he also published a history of Holstein, and a translation of the Gulistan (*Persianisches Rosenthal*, Schleswig, 1654), to which was appended a translation of the fables of Lokman. A French version of the *Beschreibung* was published by Wicquefort (1679), and an English version (1662, 2d ed. 1669) by John Davies of Kidwelly.

The embassy to which Olearius was attached made two different journeys. The first (22d October 1633 to 6th April 1635) was by Hamburg, Lübeck, Riga, Dorpat (five months' stay), Revel, Narva, Ladoga, and Novgorod to Moscow, and back again by a somewhat different route. The second (22d October 1635 to 1st August 1639) was by a similar route to Moscow, thence to the Volga, down the river to Astrakhan, across the Caspian to Nizovaya, and so on, by Shemakha, Ardebil, Sultanieh, Kaswin, &c., to Ispahan, and then back again by Resht and Lenkoran to Astrakhan, Kazan, Moscow, &c. Paul Fleming the poet and Mandelslo, whose *travels to the East Indies* are usually published with those of Olearius, accompanied the embassy.

OLEO MARGARINE. The process by which the French chemist Mège-Mouriès sought to convert ordinary animal fat into butter has already been described under BUTTER (vol. iv. p. 592). The following account of the mode of manufacture as carried on by the "Commercial Manufacturing Company" in New York is abridged from a report by Mr Victor Drummond, secretary to the British Embassy in Washington, in 1880.

Fresh fat from recently killed cattle is soaked in tepid water for one hour, then thoroughly washed with cold water, and, after having been soaked in cold water, assorted, the pieces less rich in "oil" being rejected and put aside for the manufacture of tallow. The fat thus selected is hashed up (almost minced) by machinery and melted down in water-jacketed caldrons, the water being heated by means of steam, so that the fat never becomes hotter than 124° Fahr. Through the action of this heat the fat divides into three parts, namely, shreds of membrane below, a scum of an emulsion of fat and water above, and clear oil between the two. The oil is drawn off and kept for thirty to thirty-six hours at a temperature of 85° Fahr., when a portion of the stearin and palmitin crystallizes out, while the more easily fusible components remain as a mother liquor, which is then squeezed out by hydraulic pressure. This oil, which on cooling freezes into a semi-solid fat, constitutes *oleo-margarine*, and is recommended as an excellent substitute for melted butter. Of the oil considerable quantities are worked up into imitation butter. For this purpose it is violently churned up with milk for about twenty minutes, a little arnotto being added to produce a yellow colour. The emulsion is run direct on a mass of pounded ice to cause it to solidify without crystallization. After having been again churned up with fresh milk, it is kneaded to remove the excess of water, salted (in short, manipulated as genuine churned butter is), and sent out into the market.

The report includes a comparative analysis of real and of the Commercial Company's imitation butter, of which the following is a somewhat condensed copy:—

		Real Butter.	Imitation.
1.	Glycerides of non-volatile fatty acids	51·4	56·3
2.	Glycerides of butyric and other volatile acids	7·4	1·8
3.	Caseine	0·2	0·6
	Salt	5·1	5·1
	Water	23·8	24·9

Oleo-margarine,—that is, ordinary fat minus part of the palmitin and stearin—is necessarily somewhat richer in those components (2) which are characteristically predominant in butter, but still falls far short of what real butter naturally contains. The physiological action of these butter-glycerides, as we may call them, has never been made out; possibly they may account to some extent for butter being more easily digestible than ordinary fat.

Hehner and Angell have the merit of being the first to work out an easy and straightforward method for detecting (considerable) admixtures of ordinary animal fat, and consequently also of such things as oleo-margarine, with real butter. It consists in determining the percentage of insoluble and non-volatile acids contained in the previously dehydrated and filtered article. By their *modus operandi* all ordinary animal fats yield close upon 95 per cent., while genuine butter yields only 86·5 to 87·5, at most 89 per cent., of fixed fatty acids. Easier and more decisive is the method of Reichert, who saponifies 2·5 grammes of the dry filtered article with 1 gramme of caustic potash dissolved in alcohol, expels the alcohol, decomposes the soap, after addition of 50 cubic centimetres of water, with 20 c.c. of dilute sulphuric acid (1 vol. of vitriol, 10 vol. of water), and distils off (exactly) 50 c.c., to determine therein the volatile acids by ascertaining the volume of a dilute standard solution of caustic alkali which is required to neutralize them. Real butter (per 2·5 grammes) yields 12 to 13 milligrammes, ordinary fats only 1·8 to 2·7, of volatile acids, calculated as butyric, $C_4H_8O_2$.

OLERON, an island lying off the west coast of France, opposite the mouths of the Charente and Seudre, and included in the department of the Charente-Inférieure, has an area of 59 square miles. It is about 18 miles in length from north-west to south-east, and 7 in extreme breadth; the width of the strait separating it from the mainland

is at one point less than a mile. The greater part of the island is very fertile, but there are also some extensive salt marshes, from which a considerable quantity of salt is made. The chief products are corn, wine, fruit, and vegetables. The population of the island, which is mostly Protestant and supplies excellent sailors, numbered 18,244 in 1881; that of the chief town, Château d'Oleron, on the south-east coast, was 1727. Other towns are Saint-Georges d'Oleron (4943) and Saint-Pierre d'Oleron (1535). Oleron, the Uliarus Insula of Pliny, gave its name to a mediæval code of maritime laws, for the origin and history of which see SEA LAWS.

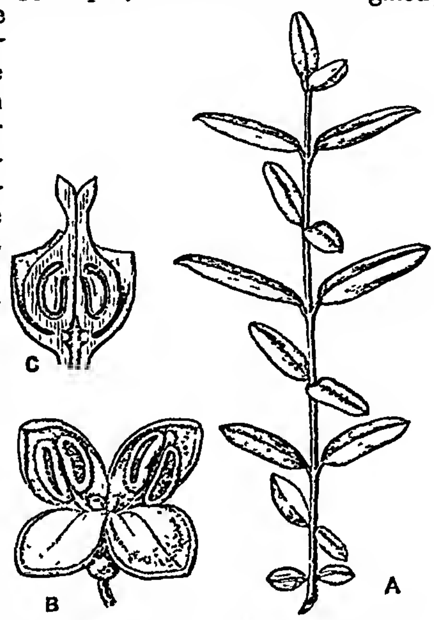
OLGA, wife of Igor, prince of Kieff, and afterwards (from 945) regent for Sviatoslaf her son, was baptized at Constantinople about 955 and died about 969. She was afterwards canonized in the Russian church, and is now commemorated on 11th July. See RUSSIA.

OLIVA, FERNAN PEREZ DE, Spanish man of letters, one of the earliest writers of didactic prose in that language, was born at Cordova about 1492, and, after studying at Salamanca, Alcalá, Paris, and Rome, was appointed to the chair of moral philosophy at Salamanca, where he died in 1530. His principal work, a *Dialogue on the Dignity of Man*, which he did not live to complete, was finished by Francisco Cervantes de Salazar, and published in 1546. His metrical translations from Euripides and Plautus are unimportant.

OLIVARES, GASPARO DE GUZMAN, CONDE DUQUE DE (1587-1645), Spanish statesman, was born at Rome on 6th January 1587, where his father, Count Enrique, who afterwards became viceroy successively of Sicily and Naples, was at the time ambassador to Pope Sixtus V. His grandfather, Count Pedro (1502-1562), had been a prominent figure at the courts both of Charles V. and of Philip II. After studying at Salamanca Olivares received, through the influence of his uncle the duke of Ueeda, the appointment of gentleman of the bedchamber to the prince of Asturias. By his winning manners and valued, if not always very creditable, services he so ingratiated himself with the heir-apparent that the latter, on his accession as Philip IV. in 1621, forthwith made him his prime minister, conferring on him the title of Duque de San Lucar de Barrameda. It was the ambition of Olivares to regain for his country by arms and intrigue the influence it had formerly possessed in Europe, but his abilities, great as they were, were very unequally matched with those of Richelieu, his rival in policy, and twenty-two years of almost autocratic power accordingly had no other result than deep national humiliation as well as personal disgrace (see SPAIN). The expedients to which he was compelled to resort in order to raise money for his long and unsuccessful war with the Dutch and for the support of his armies in Germany and Italy raised throughout the Spanish peninsula a spirit of discontent, which came to a crisis in 1640, when Catalonia rebelled, calling in the aid of the French, and Portugal declared its independence, electing the duke of Braganza as king. All his attempts at pacification having failed, the enemies of Olivares succeeded in supplanting him in the king's favour in 1643. He was banished to Toro (Zamora) where he died in 1645.

See De la Rocca, *Hist. du ministère du Comte-duc d'Olivares* (Cologne, 1673).

OLIVE (*Olea europæa*), the well-known plant that yields the olive oil of commerce, belongs to a section of the natural order *Oleaceæ*, of which it has been taken as the type. The genus *Olea* includes about thirty-five species, very widely scattered, chiefly over the Old World, from the basin of the Mediterranean to South Africa and New Zealand. The wild olive, or oleaster, is a small tree or bush of rather straggling growth, with thorny branches and opposite oblong pointed leaves, dark greyish-green above and, in the young state, hoary beneath with whitish scales; the small white flowers, with four-cleft calyx and corolla, two stamens, and bifid stigma, are borne on the last year's wood, in racemes springing from the axils of the leaves; the drupaceous fruit is small in the wild plant, and the fleshy pericarp, which gives the garden olive its economic value, is hard and comparatively thin. In the cultivated forms the tree acquires a more compact habit, the branches lose their spinous character, while the young shoots become more or less angular; the leaves are always hoary on the under-side, and are generally lanceolate in shape, though varying much in breadth and size in the different kinds. The fruit is subject to still greater alterations of form and colour; usually oval or nearly globular, in some sorts it is egg-shaped, in others much elongated; while the dark hue that it commonly assumes when ripe is exchanged in many varieties for violet, green, or almost white. At present the wild olive is found in most of the countries around the Mediterranean, extending its range on the west to Portugal, and eastward to the vicinity of the Caspian, while, locally, it occurs even in Afghanistan. An undoubted native of Syria and the maritime parts of Asia Minor, its abundance in Greece and the islands of the Archipelago, and the frequent allusions to it by the earliest poets, seem to indicate that it was there also indigenous; but in localities remote from the Levant it may have escaped from cultivation, reverting more or less to its primitive type. It shows a marked preference for calcareous soils and a partiality for the sea-breeze, flourishing with especial luxuriance on the limestone slopes and crags that often form the shores of the Greek peninsula and adjacent islands.



A, *Olea europæa* (from nature) B, opened flower; C, vertical section (after Luerssen, *Med.-Pharm. Botanik*, 1882)

The varieties of olive known to the modern cultivator are extremely numerous,—according to some authorities, equalling or exceeding in number those of the vine. In France and Italy at least thirty kinds have been enumerated, but comparatively few are grown to any large extent. None of these can be safely identified with ancient descriptions, though it is not unlikely that some of the narrow-leaved sorts that are most esteemed may be descendants of the famed "Licinian" (see below). Italy retains its old pre-eminence in olive cultivation; and, though its ancient Gallic province now excels it in the production of the finer oils, its fast-improving culture may restore the old prestige. The broad-leaved olive trees of Spain bear a larger fruit, but the pericarp is of more bitter flavour and the oil of ranker quality. The olive tree, even when free increase is unchecked by pruning, is of very slow growth; but, where allowed for ages its natural development, the trunk sometimes attains a considerable diameter. De Candolle records one exceeding 23 feet in girth, the age being supposed to amount to seven centuries. Some old Italian olives have been credited with an antiquity reaching back

to the first years of the empire, or even to the days of republican Rome; but the age of such ancient trees is always doubtful during growth, and their identity with old descriptions still more difficult to establish. The tree in cultivation rarely exceeds 30 feet in height, and in France and Italy is generally confined to much more limited dimensions by frequent pruning. The wood, of a yellow or light greenish-brown hue, is often finely veined with a darker tint, and, being very hard and close-grained, is valued by the cabinetmaker and ornamental turner.

The olive is propagated in various ways, but cuttings or layers are generally preferred; the tree roots in favourable soil almost as easily as the willow, and throws up suckers from the stump when cut down. Branches of various thickness are cut into lengths of several feet each, and, planted rather deeply in manured ground, soon vegetate; shorter pieces are sometimes laid horizontally in shallow trenches, when, covered with a few inches of soil, they rapidly throw up sucker-like shoots. In Greece and the islands grafting the cultivated tree on the oleaster is a common practice. In Italy embryonic buds, which form small swellings on the stems, are carefully excised and planted beneath the surface, where they grow readily, these "uovoli" soon forming a vigorous shoot. Occasionally the larger boughs are inarched, and young trees thus soon obtained. The olive is also sometimes raised from seed, the oily pericarp being first softened by slight rotting, or soaking in hot water or in an alkaline solution, to facilitate germination. The olives in the East often receive little attention from the husbandman, the branches being allowed to grow freely and without curtailment by the pruning-knife; water, however, must be supplied in long droughts to ensure a crop; with this neglectful culture the trees bear abundantly only at intervals of three or four years; thus, although wild growth is favourable to the picturesque aspect of the plantation, it is not to be recommended on economic grounds. Where the olive is carefully cultivated, as in Languedoc and Provence, it is planted in rows at regular intervals, the distance between the trees varying in different "olivettes," according to the variety grown. Careful pruning is practised, the object being to preserve the flower-bearing shoots of the preceding year, while keeping the head of the tree low, so as to allow the easy gathering of the fruit; a dome or rounded form is generally the aim of the pruner. The spaces between the trees are occasionally manured with rotten dung, or other nitrogenous matter; in France woollen rags are in high esteem for this purpose. Various annual crops are sometimes raised between the rows, and in Calabria wheat even is grown in this way; but the trees are better without any intermediate cropping. Latterly a dwarf variety, very prolific, and with green fruit, has come into favour in certain localities, especially in America, where it is said to have produced a crop two or three seasons after planting. The ordinary kinds do not become profitable to the grower until from five to seven years after the cuttings are placed in the olive-ground. Apart from occasional damage by weather or organic foes, the olive crop is somewhat precarious even with the most careful cultivation, and the large untended trees so often seen in Spain and Italy do not yield that certain income to the peasant proprietor that some authors have attributed to them; the crop from these old trees is often enormous, but they seldom bear well two years in succession, and in many instances a luxuriant harvest can only be reckoned upon every sixth or seventh season. The fruit when ripe is, by the careful grower, picked by hand and deposited in cloths or baskets for conveyance to the mill; but in many parts of Spain and Greece, and generally in Asia, the olives are beaten down by poles, or by shaking the boughs, or even allowed to drop naturally, often lying on the ground until the convenience of the owner admits of their removal; much of the inferior oil owes its bad quality to the carelessness of the proprietor of the trees. In southern Europe the olive harvest is in the winter months, continuing for several weeks; but the time varies in each country, and also with the season and the kinds cultivated. The amount of oil contained in the fruit differs much in the various sorts; the pericarp usually yields from 60 to 70 per cent. The ancient agriculturists believed that the olive would not succeed if planted more than a few leagues from the sea (Theophrastus gives 300 stadia as the limit), but modern experience does not confirm the idea, and, though showing a preference for the coast, it has long been grown far inland. A calcareous soil, however dry or poor, seems best adapted to its healthy development, though the tree will grow in any light soil, and even on clay if well drained; but, as remarked by Pliny, the plant is more liable to disease on rich soils, and the oil is inferior to the produce of the poorer and more rocky ground the species naturally affects. The olive suffers greatly in some years from the attacks of various enemies. A fungoid growth has at times infested the trees for several successive seasons, to the great damage of the plantations. A species of coccus, *C. oleæ*, attaches itself to the shoots, and certain lepidopterous caterpillars feed on the leaves, while the "olive-fly" attacks the fruit. In France the olivettes suffer occasionally from frost; in the early part of the last century many trees were cut to the ground by a winter of exceptional severity. Gales and long-continued rains during the gathering season also cause mischief.

The unripe fruit of the olive is largely used in modern as in ancient times as an article of dessert, to enhance the flavour of wine, and to renew the sensitiveness of the palate for other viands. For this purpose the fruit is picked while green, soaked for a few hours in an alkaline ley, washed well in clean water, and then placed in bottles or jars filled with brine; the Romans added *amurca* to the salt to increase the bitter flavour of the olives, and at the present day spices are sometimes used.

The leaves and bark of the tree are employed in the south, as a tonic medicine, in intermittent fever. A resinous matter called "olive gum," or Lucca gum, formed by the exuding juice in hot seasons, was anciently in medical esteem, and in modern Italy is used as a perfume.

In England the olive is not hardy, though in the southern counties it will stand ordinary winters with only the protection of a wall, and will bear fruit in such situations; but the leaves are generally shed in the autumn, and the olives rarely ripen.

The genus *Olea* includes several other species of some economic importance. The olive of America, *O. americana*, a rather small tree, growing in the southern parts of the United States, with broadly-lanceolate leaves and compound racemes of small white fragrant flowers, is remarkable for the extreme hardness of its wood, which, resisting ordinary tools, is called devil-wood by the southern lumberers and squatters. *O. paniculata* is a larger tree, attaining a height of 50 or 60 feet in the forests of Queensland, and yielding a hard and tough timber. The yet harder wood of *O. laurifolia*, an inhabitant of Natal, is the black ironwood of the South African colonist. The white or yellowish sweet-scented flowers of *O. fragrans*, a Chinese species, are employed to communicate their aroma to some of the finer teas; the oblong serrated leaves are said to be used for the adulteration of inferior kinds. Some other species of olive furnish hard and close-grained wood, but are not yet of much general interest.

At what remote period of human progress the wild oleaster passed under the care of the husbandman and became the fruitful garden olive it is impossible to conjecture;—history and tradition are alike silent regarding the origin of most of the more valued plants of cultivation, and we know little more of the later evolution of the olive than of the remoter genealogies of our present wheat and maize. The frequent reference in the Bible to the plant and its produce, its implied abundance in the land of Canaan, the important place it has always held in the economy of the inhabitants of Syria, lead us to consider that country the birthplace of the cultivated olive. An improved variety, possessed at first by some small Semitic sept, it was probably slowly distributed to adjacent tribes; and, yielding profusely, with little labour, that oily matter so essential to healthy life in the dry hot climates of the East, the gift of the fruitful tree became in that primitive age a symbol of peace and goodwill among the warlike barbarians. At a later period, with the development of maritime enterprise, the oil was conveyed, as an article of trade, to the neighbouring Pelasgic and Ionian nations, and the plant, doubtless, soon followed.

Hehn remarks that in the Homeric world, as depicted in the *Iliad*, olive oil is known only as a luxury of the wealthy,—an exotic product, prized chiefly for its value in the heroic toilet; the warriors anoint themselves with it after the bath, and the body of Patroclus is similarly sprinkled; but no mention of the culture of the plant is made, nor does it find any place on the Achillean shield, on which a vineyard is represented. But, although no reference to the cultivation of the olive occurs in the *Iliad*, the presence of the tree in the garden of Alcinous and other familiar allusions show it to have been known when the *Odyssey* was written. Whenever the introduction may have taken place, all tradition points to the limestone hills of Attica as the seat of its first cultivation on the Hellenic peninsula. When Poseidon and Athene contended for the future city, an olive sprang from the barren rock at the bidding of the goddess, the patron of those arts that were to bring undying influence to the rising state. That this myth has some relation to the first planting of the olive in Greece seems certain from the remarkable story told by Herodotus of the Epidaurians, who, on their crops failing, applied for counsel to the Delphic oracle, and were enjoined to erect statues to Damia and Auxesia (symbols of fertility) carved from the wood of the true garden olive, then possessed only by the Athenians, who granted their request for a tree on condition of their making an annual sacrifice to Athene, its patron; they thus obeyed the command of the Pythian, and their lands became again fertile. The sacred tree of the goddess long stood on the Acropolis, and, though destroyed in the Persian invasion, sprouted again from the root,—some suckers of which were said to have produced those olive trees of the Academy in an after age no less revered. By the time of Solon the olive had so spread that he found it necessary to enact laws to regulate the cultivation of the tree in Attica, from which country it was probably distributed gradually to all the Athenian allies and tributary states. To the Ionian coast, where it abounded in the time of Thales, it may have been in an earlier age brought by Phœnician vessels; some of the Sporades may have received it from the same source; the olives of Rhodes and Crete had perhaps a similar origin. Samos, if we may judge from the epithet of Æschylus (ἐλαιόφυτος), must have had the fruitful plant long before the Persian wars. It is not unlikely that the valued tree was taken to Magna Græcia by the first Achæan colonists, and the assertion of Pliny (quoted from Fenestella), that no olives existed in Italy in the reign of Tarquinius Priscus, must be received with the caution due to many statements of that industrious compiler. In Latin Italy the cultivation seems to have spread slowly, for it was not until the consulship of Pompey that the production of oil became sufficient to permit of its exportation. In Pliny's time it was already grown abundantly in the two Gallic provinces and in Spain; indeed, in the earlier days of Strabo the Ligurians supplied the Alpine barbarians with oil, in exchange for the wild produce of their mountains; the plant may have been introduced into those districts by Greek settlers in a previous age. Africa was indebted for the olive mainly to Semitic agencies. In Egypt the culture never seems to have made much progress; the oil found in Theban tombs was probably imported from Syria. Along the southern shore of the great inland sea the tree was carried by the Phœnicians, at a remote period, to their numerous colonies in Africa,—though the abundant olives of Cyrene, to which allusion is made by Theophrastus, and the glaucous foliage of whose descendants still clothes the rocks of the deserted Cyrenaica, may have been the offspring of Greek plants brought by the first settlers. The tree was most likely introduced into southern Spain, and perhaps into Sardinia and the Balearic Islands, by Phœnician merchants; and, if it be true that old olive trees were found in the Canaries on their rediscovery by mediæval navigators, the venerable trees probably owed their origin to the same enterprising pioneers of the ancient world. De Candolle says that the means by which the olive was distributed to the two opposite shores of the Mediterranean are indicated by the names given to the plant by their respective inhabitants,—the Greek ἐλαία passing into the Latin *olea* and *oliva*, that in its turn becoming the *ulivo* of the modern Italian, the *olivo* of the Spaniard, and the *olive*, *olivier*, of the French, while in Africa and southern Spain the olive retains appellatives derived from the Semitic *zait* or *seit*; but the complete subjugation of Barbary by the Saracens sufficiently accounts for the prevalence of Semitic forms in that region; and *aceytuno* (Arab. *zeitûn*), the Andalusian name of the fruit, locally given to the tree itself, is but a vestige of the Moorish conquest. Yielding a grateful substitute for the butter and animal fats consumed by the races of the north, the olive, among the southern nations of antiquity, became an emblem not only of peace but of national wealth and domestic plenty; the branches borne in the Panathenæa, the wild olive spray of the Olympic victor, the olive crown of the Roman conqueror at ovation, and those of the equites at their imperial review alike typified gifts of peace that, in a barbarous age, could be secured by victory alone. Among the Greeks the oil was valued as an important article of diet, as well as for its external use. The Roman people employed it largely in food and cookery,—the wealthy as an indispensable adjunct to the toilet; and in the luxurious days of the later empire it became a favourite axiom that long and pleasant life depended on two fluids, "wine within and oil without." Pliny vaguely describes fifteen varieties of olive cultivated in his day,—that called the "Licinian" being held in most esteem, and the oil obtained from it at Venafrum in Campania the finest known to Roman connoisseurs; the produce of Istria and Bætica was regarded as second only to that of the Italian peninsula. The *gourmet* of the empire valued the unripe fruit, steeped in brine, as a provocative to the palate, no less than his modern representative; and pickled olives, retaining their characteristic flavour, have been found among the buried stores of Pompeii. The bitter juice or refuse deposited during expression of the oil (called *amurca*), and the astringent leaves of the tree have many virtues attributed to them by ancient authors. The oil of the bitter wild olive was employed by the Roman physicians in medicine, but does not appear ever to have been used as food or in the culinary art.

In modern times the olive has been spread widely over the world; and, though the Mediterranean lands that were its ancient home still yield the chief supply of the oil, the tree is now cultivated successfully in many regions unknown to its early distributors. Soon after the discovery of the American continent it was conveyed thither by the Spanish settlers. In Chili it flourishes as luxuriantly as in its native land, the trunk sometimes becoming of large girth, while oil of fair quality is yielded by the fruit. To Peru it was carried at a later date, but has not there been equally successful. Introduced into Mexico by the Jesuit missionaries of the 17th century, it was planted by similar agency in Upper California, where it has prospered latterly under the more careful management of the Anglo-Saxon conqueror. Its cultivation has also been attempted in the south-eastern States, especially in Carolina, Florida, and Mississippi. In the eastern hemisphere the olive has been established in many inland districts, which would have been anciently considered ill adapted for its culture. To Armenia and Persia it was known at a comparatively early period of history, and many olive-yards now exist in Upper Egypt, where the cultivation is said to be increasing. The tree has lately been introduced into Chinese agriculture, while in the present generation it promises to become an important addition to the resources of the Australian planter. In Queensland the olive has found a climate specially suited to its wants; in South Australia, near Adelaide, it also grows vigorously; and there are probably few coast districts of the vast island-continent where the tree would not flourish. It has likewise been successfully introduced into some parts of the Cape Colony. (C. P. J.)

OLIVES, MOUNT OF, or MOUNT OLIVET (ὄρος ἐλαιῶνος or τῶν ἐλαιῶν, in Mishna and Midrash הַר הַזֵּיתִים or הַר הַמִּשְׁחָה, now Jebel al-Ṭûr), is the hill facing the Temple Mount on the east, and separated from it by the Kidron (see vol. xiii. p. 636 *sq.*). Here our Lord sat when He delivered His great eschatological address (Mark xiii. 3). That the ascension took place from the summit of the Mount of Olives is not necessarily implied in Acts i. 12, and appears to be excluded by Luke xxiv. 50, for Bethany lies at the back of the hill and almost a mile from the top. But since Constantine erected the basilica of the ascension on the spot marked by a certain sacred cave (Euseb., *V. Const.*, iii. 41) the site of the ascension has been placed here and marked by a succession of churches. The present building is quite modern. Close to the chapel of the ascension is the vault of St Pelagia, and a little way down the hill is the labyrinth of rock-hewn sepulchral chambers now called the "Tombs of the Pro-

phets." A chapel bearing the name of 'Omar, and said to occupy the place where he encamped when Jerusalem surrendered to the Moslems, formerly stood beside the church of the ascension (Moḳaddasī).

OLIVETANS, a monastic order, that of Our Lady of Monte Oliveto, following the Benedictine rule, was founded about the year 1313 by Bernardo Tolomei of Siena (see MONACHISM). The mother-house at Monte Oliveto Maggiore, about 19 miles to the south of Siena, is a favourable specimen of a great Benedictine monastery; the church and library contain some fine inlaid work by Fra Giovanni da Verona (1502-1505), and the court has celebrated frescos by Luca Signorelli and Ant. Bazzi (Soddoma).

OLMSTED, DENISON (1791-1859), man of science, was born at East Hartford, Connecticut, U.S.A., on 18th June 1791, and became a student of Yale, where he graduated in 1813, and acted as college tutor from 1815 to 1817. In the latter year he was appointed to the chair of chemistry, mineralogy, and geology in the university of North Carolina. This chair he exchanged for that of mathematics and physics at Yale in 1825; in 1836, when this professorship was divided, he retained that of astronomy and natural philosophy. He died at New Haven, Connecticut, on 13th May 1859.

His first publication (1824-25) was the *Report* of his geological survey of the State of North Carolina. It was followed by various text-books on natural philosophy and astronomy, but he is chiefly known to the scientific world for his observations on hail (1830), on meteors, and on the aurora borealis. For his conclusions on the last-named subject see vol. viii. of the *Smithsonian Contributions*.

OLMÜTZ (Slavonic, *Olomouc* or *Holomauc*), the second city and the ecclesiastical metropolis of Moravia, and one of the strongest fortresses in the Austrian empire, is situated on the March, about 110 miles to the north of Vienna. Like most Slavonic towns, it contains several large squares, the chief of which is adorned with a trinity column, 115 feet high. The most prominent church is the cathedral, a Gothic building of the 14th century, containing the tomb of King Wenceslaus III., who was murdered here in 1306. The principal secular buildings are the archbishop's palace, the town-house, the arsenal, the barracks, and the various schools, convents, and hospitals. The old university is now represented by a theological faculty attended by about a hundred students. Its library formerly possessed an important collection of Slavonic works, which was carried off by the Swedes during the Thirty Years' War. There is also an industrial museum. The manufactures of Olmütz itself are comparatively insignificant, but it is important as the emporium of a busy mining and industrial district and as a mart for Russian and Moldavian cattle. The population in 1880 was 20,176, besides which there is a garrison of about 6000 men. German is the predominant language. The chief part of the fortifications, which were originally constructed in the time of the wars with Frederick the Great, consists of a girdle of about twenty outlying forts. In case of attack the adjacent district can be flooded with the water of the March.

Olmutz is said to occupy the site of a Roman fort founded in the imperial period, the original name of which, *Mons Julii*, has been gradually corrupted to the present form. At a later period Olmutz was long the capital of the Slavonic kingdom of Moravia, but it ceded that position to Brünn in 1640. During the Thirty Years' War it was occupied by the Swedes for eight years, and in 1758 it successfully resisted Frederick the Great during a siege of seven weeks. In 1848 Olmütz was the scene of the emperor Ferdinand's abdication, and in 1850 of an important conference, for an account of which see GERMANY and AUSTRIA. The bishopric of Olmütz was founded in 1073, and raised to the rank of an archbishopric in 1777. The bishops were created princes of the empire in 1588. The archbishop is the only one in the Austrian empire who is elected by the cathedral chapter.

OLONETZ, a government of north-western Russia, extending from Lake Ladoga almost to the White Sea, is bounded on the W. by Finland, on the N. and E. by Archangel and Vologda, and on the S. by Novgorod. The area is 57,440 square miles. Its north-western portion belongs orographically and geologically to the Finland region; it is covered with hills reaching 1000 feet in height, and with numberless smaller ridges and hollows running from north-west to south-east. The rest of the government is a flat plateau sloping towards the marshy lowlands of the south. The geological structure is very varied. Granites, syenites, and diorites, covered with Laurentian metamorphic slates, occur extensively in the north-west. Near Lake Onega they are covered with Devonian sandstones and limestones, yielding marble and sandstone for building; to the south of that lake the Carboniferous limestones and clays make their appearance. The whole is covered by vast beds of boulder-clay,—the bottom moraine of the great ice-sheet of the Glacial period. The entire region bears traces of glaciation, either in the shape of scratching and elongated grooves on the rocks, or of eskers (*åsar*, *selgas*) running parallel to the glacial striation. Numberless lakes, more than 2000 being already laid down on the maps, still occupy the depressions of the surface, while a great many more have left evidence of their past existence in the shape of extensive marshes. Lake Onega covers 3765 square miles and reaches a depth of 125 fathoms. Lakes Seg, Vyg, Lache, and Vodlo cover from 140 to 480 square miles each, and their crustacean fauna shows a former connexion with the Arctic Ocean. The south-eastern part of Lake Ladoga belongs also to the government of Olonetz. Altogether, the area covered by lakes, marshes, and rivers reaches one-fifth of the whole surface. The rivers belong to the Baltic and White Sea basins. To the former system belong Lakes Ladoga and Onega, which are connected by the Svir and receive numerous streams; of these the Vytegra, which communicates with the Mariinsk canal-system, and the Oyat, an affluent of Lake Ladoga, are important for navigation. No less than 4,000,000 cwts. of timber, fire-wood, stone, metal, and flour are annually shipped on waters belonging to this government. The Onega river, which has its source in the south-eastern parts of the government and flows into the White Sea, is of minor importance. Seventy per cent. of the area of Olonetz is occupied by forests; those of the crown, maintained for shipbuilding purposes, cover more than 800,000 acres.

The climate is harsh and moist, the average yearly temperature at Petrozavodsk (61° 8′ N. lat.) being 33°·6 Fahr. (12°·0 in January, 57°·4 in July); the thermometer rarely falls under − 30° Fahr. The population, which numbered 321,250 in 1881 (296,400 in 1873), is made up of Great Russians and Finns; Karelians and Tchudis are estimated at about 52,000 each. The people mostly belong to the Greek Church, or are Nonconformists Sparse though it is, the population is still too dense in certain places when the smallness of the area available for agriculture (only the summits of the *selgas*, or elongated ridges separated by marshes) is taken into account. The villages are mostly small, and in several parts of the government are still aggregated into federations of communes. Only 765,000 acres were under crops in 1877. Cattle and horse breeding, which are much interfered with by plague, are insignificant. The chief source of wealth is the timber-trade, next to which come fishing and hunting. Mushrooms and berries are exported to St Petersburg. There are also quarries and iron-mines, and some 1600 men find employment in saw-mills, tanneries, iron-works, distilleries, and flour-mills. More than one-fifth of the entire male population leave their homes every year in search of employment. The government is divided into seven districts, the chief towns of which are the capital Petrozavodsk (12,000 inhabitants), Kargopol, Olonetz, Povyenets, Vytegra, and Pudozh. Olonetz includes the "Olonetz Mining District," a territory belonging to the crown, which covers 432 square miles and extends partly into the Serdobol district of Finland. The iron-works were begun by Peter I. in 1701-14. There is a population of about 60,000, who were, until 1864, serfs to the crown.

Olonetz was colonized by Novgorod in the 11th century, and though it suffered much from Swedish invasion its towns soon became wealthy trading centres Ivan III. annexed it to the principality of Moscow.

OLORON-SAINTE-MARIE, the chief town of an arrondissement in the department of Basses-Pyrénées, France, lies about 21 miles south-west of Pau, at the confluence of the mountain torrents (locally known as "gaves") Aspe and Ossau, which unite to form the Oloron, a tributary of the Pau. The united population of Oloron and of Sainte-Marie, on the opposite bank of the Aspe, is 7746. Oloron, curiously clustered on the summit and slopes of a steep hill, has remains of old ramparts and pleasant promenades with beautiful views. The only building of interest, the church of the Sainte-Croix, belongs mainly to the 11th century; it contains a large altar of gilded wood, constructed in the Spanish style of the 17th century. The church of Sainte-Marie, which formerly served as the cathedral of Oloron, is a medley of various styles from the 11th to the 15th century, and its sculptures are more antique than tasteful. The fairs and markets of Oloron for cattle, horses, wool, and hams are much frequented. It manufactures woollen goods, textile fabrics, and caps (bérets), and has also tanyards and flour-mills.

Oloron, formerly Iluro, an ancient episcopal town, was destroyed by the Saracens, and afterwards by the Normans, and was rebuilt in 1080 by the viscount of Béarn. At the Reformation the place became a centre of Catholic reaction. In the 17th century it carried on a considerable trade with Aragon, until the Spaniards, jealous of its prosperity, pillaged the establishments of the Oloron merchants at Saragossa in 1694,—a disaster from which it only slowly recovered. The bishopric was suppressed in 1790.

OLYBRIUS, Roman emperor from 11th July to 23d October 472, was a member of the Anician family and a native of Rome, where he lived until the sack of Genseric in 455. He then went to Constantinople, where in 464 he was made consul, and about the same time married Placidia, daughter of Valentinian III. In 472 he was sent to Italy by the emperor Zeno to assist Anthemius against Ricimer, but, having entered into negotiations with the latter, was himself proclaimed emperor, and, on the murder of his rival, ascended the throne unopposed. His reign was as uneventful as it was brief. He died from natural causes.

OLYMPIA. The purpose of this article is to give a short but clear summary for English readers of the principal results obtained by the German exploration of Olympia in 1875-81, and recorded in the five volumes of the *Ausgrabungen* published at Berlin. While the sketch is necessarily confined to salient features and essential points, two aims have been kept in view:—first, to omit nothing that is important to the general study of antiquity; secondly, to make the outlines, however slight, sufficiently precise and consecutive to serve as an introduction to a more special archæological study. Having enjoyed the advantage of seeing the excavations, under the courteous guidance of Dr. Treu (then at the head of the German archæological mission), at the close of the third campaign in June 1878, the writer is able to speak of the ground not from a book-knowledge alone. A few words must be premised on the geography and history of Olympia, so far as an acquaintance with the broader aspects of these must be presupposed in an intelligent survey of the topography.

On the western side of the Peloponnesus, the Alpheus, the chief river of the peninsula, issues from the central highlands of Arcadia. Increased by the tributary streams of the Ladon and the Erymanthus, it then flows, in a broad bed, between hills which gradually subside, until it enters on the sandy levels of the coast, and reaches the sea between two long lagoons. The district traversed by its lower course is that which was anciently called *Pisatis*, extending from the mouth of the Alpheus to the Erymanthus, between Elis on the north and Triphylia on the south. The alpine character of Arcadia has here entirely disappeared. There are few steep cliffs or rocks; the banks of the river are generally covered with alluvial earth; and rich vegetation prevails, with abundance of evergreen trees and bushes. Cornfields, vines, and currants are plentiful; even the sandy tracts, coated with a rich mud, prove fertile. Cattle-breeding prospers on the higher ground of Mount Pholoe; and the lagoons yield fish. The stay-at-home character of the inhabitants which the historian Polybius notices was a natural result of their environment. While the region was ill-suited to the secure development of a strong state, it was eminently favourable to a life of quiet industry, and was open on every side to peaceful intercourse with the neighbouring country. The ancient landing-place was at the mouth of the Alpheus,—about 3000 metres above the present mouth. The site of the modern town of Pyrgos—then much nearer the sea—may be that of the ancient Dyspontium. The only modern landing-place is at Catácolo, where a mole has been constructed by French engineers. It is visited by coasting steamers, being one of the export-stations of the currant-trade. In the valley of the Alpheus, a few miles east of the point at which it enters on the flat seaboard, there existed a primitive shrine of the Pelasgian Zeus. As in other places associated with his worship, the low range bounding the Alpheus on the north was called *Olympus*, while the name of *Ossa* was given to the hill-boundary of the valley on the south. When the worship of the Hellenic Zeus had been established on this spot, the place acquired the name of *Olympia*.

Olympia is on the right or north bank of the Alpheus (now the Ruphia), about 16 kilometres east in a straight line from the modern Pyrgos. The course of the river is here from east to west, and the average breadth of the valley is about 1000 metres. At this point a small stream, the ancient Cladeus, flows from the north into the Alpheus. The area known as Olympia is bounded on the west by the Cladeus, on the south by the Alpheus, on the north by the low heights which shut in the Alpheus valley, and on the east by the ancient race-courses. One group of these heights terminates in a conical hill, about 122 metres high, which is cut off from the rest by a deep cleft, and descends abruptly on Olympia. This hill is the famous *Cronion* (Κρόνιον), sacred to Cronus, the father of Zeus.

The natural situation of Olympia is, in one sense, of great beauty. When Lysias, in his *Olympiacus* (spoken here), calls it "the fairest spot of Greece," he was doubtless thinking also—or perhaps chiefly—of the masterpieces which art, in all its forms, had contributed to the embellishment of this national sanctuary. But even now the praise seems hardly excessive to a visitor who, looking eastward up the valley of Olympia, sees the snow-crowned chains of Erymanthus and Cyllene rising in the distance. The valley, at once spacious and definite, is a natural *temenos*. Nowhere could the Greek Zeus be more fitly honoured by the display of human gifts, physical or mental; nowhere could the divided communities of Hellas find a more convenient or attractive place of peaceful re-union.

The importance of Olympia in the history of Greece has, in fact, this twofold character: it is at once religious and political. The religious associations of the place date from the prehistoric age, when, before the states of Elis and Pisa had been founded, predecessors—perhaps ancestors—of the Hellenes worshipped the "heaven-father" in this valley. The political associations may be said to date from the time when the Achæans founded Pisa, and combined the Pelasgian worship of the god Zeus with a local cult of their own ancestor, the hero Pelops. It was then, and in honour of Pelops, that games were probably instituted for the first time at Olympia. The addition of Hera and of the mother of the gods to the specially honoured deities must have come early in the Hellenic period. Elis and

Pisa were at first associated, as equal states, in the control of the Olympian festival. Sixteen women, representing eight towns of Elis and eight of Pisatis, wove the festal peplus for the Olympian Hera. Olympia thus became the centre of an ἀμφικτυονία, or federal league under religious sanction, for the west coast of the Peloponnesus, as Delphi was for its neighbours in northern Greece. It suited the interests of Sparta to join this amphictyony; and, before the regular catalogue of Olympic victors begins in 776 B.C., Sparta had formed an alliance with Elis. Aristotle saw in the temple of Hera at Olympia a bronze disk, recording the traditional laws of the festival, on which the name of Lycurgus stood next to that of Iphitus, king of Elis. Whatever may have been the age of the disk itself, the relation which it indicates is well attested. Elis had from the first been stronger than Pisa. Elis and Sparta, making common cause, had no difficulty in excluding the Pisatans from their proper share in the management of the Olympian sanctuary. Pisa had, indeed, a brief moment of better fortune. The ascendency of Pheidon of Argos enabled him to reassert the old Achæan claim by celebrating the 28th Olympiad under the presidency of the Pisatans. This festival, from which the Eleans and Spartans were excluded, was afterwards struck out of the official register, as having no proper existence. At last, about 570 B.C., the destruction of Pisa by the combined forces of Sparta and Elis put an end to the long rivalry. Not only Pisatis, but also the district of Triphylia to the south of it, now became dependent on Elis. So far as the religious side of the festival was concerned, the Eleans had now an unquestioned supremacy. It was at Elis, in the gymnasium of the city, that candidates from all parts of Greece were tested, before they were admitted to the athletic competitions at Olympia. To have passed through the training (usually of ten months) at Elis was regarded as the most valuable preparation. Elean officials, who not only adjudged the prizes at Olympia, but decided who should be admitted to compete, marked the national aspect of their functions by assuming the title of *Hellanodicæ*.

Long before the overthrow of Pisa the list of contests at Olympia had been so enlarged and diversified as to invest the celebration with a Panhellenic character. Exercises of a Spartan type—testing endurance and strength with an especial view to war—had almost exclusively formed the earlier programme. But as early as the 25th Olympiad —*i.e.*, several years before the interference of Pheidon on behalf of Pisa—the four-horse chariot-race was added. This was an invitation to wealthy competitors from every part of the Hellenic world, and was also the recognition of a popular or spectacular element, as distinct from the skill which had a merely athletic or military interest. Horse-races were added later. For such contests the *hippodrome* was set apart. Meanwhile the list of contests on the old racecourse, the *stadion*, had been enlarged. Besides the foot-race in which the course was traversed once only, there were now the *diaulos* or double course, and the "long" foot-race (*dolichos*). Wrestling and boxing were combined in the *pancration*. Leaping, quoit-throwing, javelin-throwing, running, and wrestling were combined in the *pentathlon*.

After the conquest of Messenia Spartan ambition had turned towards Arcadia. The aim of the Spartans was nothing less than the subjugation of the entire Peloponnesus. But the decided check which the aggressors experienced in their new attempt produced a change of design. It became evident that a policy of forcible annexation could be pushed no further. Yet Sparta might at least aspire to the hegemony of the peninsula. The other states of the Peloponnesus, while remaining independent, might be virtually under Spartan control. And for the establishment of such a hegemony what agency could be more suitable than that of Olympia? In the Olympian amphictyony, Sparta, closely allied with Elis, already held a commanding position. The rising popularity of the festival was constantly tending to make Olympia the religious and social centre of Peloponnesian life—indeed, in some sense, of the Hellenic world. As the Eleans, therefore, were now the religious supervisors of Olympia, so the Spartans aimed at constituting themselves its political protectors. Their military strength—greatly superior at the time to that of any single Hellenic state—readily enabled them to do this in the most effectual manner. Spartan arms could enforce the sanction which the Olympian Zeus gave to the oaths of the amphictyones, whose federal bond was symbolized by common worship at his shrine. Spartan arms could punish any violation of that "sacred truce" which was indispensable if Hellenes from all cities were to have peaceable access to the Olympian festival. And in the eyes of all Dorians the assured dignity thus added to Olympia would be enhanced by the fact that the protectors were the Spartan Heraclidæ.

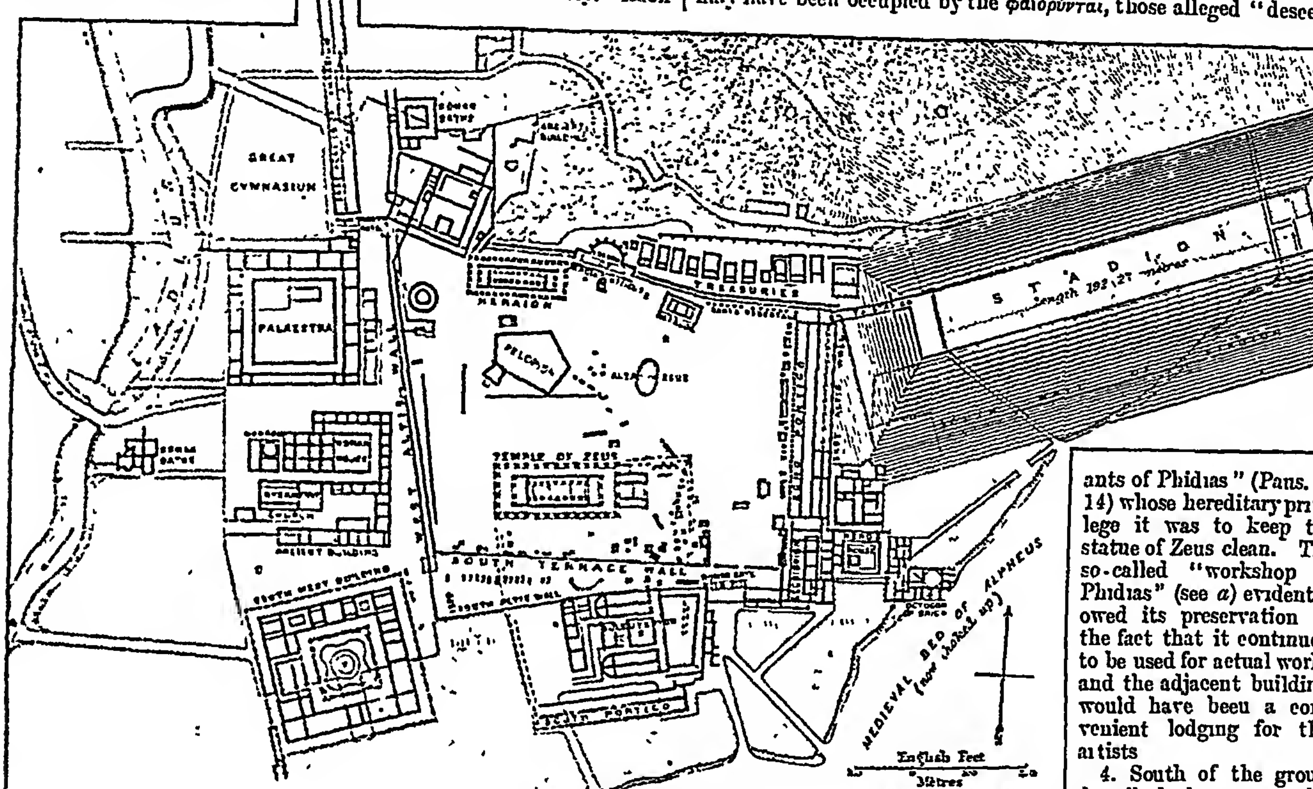
Thus, under the permanent guarantee of the strongest military power, and at the same time under auspices which, for a large part of the Greek world, were the most illustrious possible, Olympia entered on a new phase of brilliant and secure existence as a recognized Panhellenic institution. This phase may be considered as beginning after the destruction of Pisa, about 570 B.C. And so it continued to be to the last. While the details of the scene and of the festival were the subjects of endless modification or change, Olympia always remained a central expression of the Greek ideas that the body of man has a glory as well as his intellect and spirit, that body and mind should alike be disciplined, and that it is by the harmonious discipline of both that men best honour Zeus. The significance of Olympia was larger and higher than the political fortunes of the Greeks who met there, and it survived the overthrow of Greek independence. In the Macedonian and Roman ages the temples and contests of Olympia still interpreted the ideal at which free Greece had aimed. Philip of Macedon and Nero are, as we shall see, among those whose names have a record in the Altis. Such names are typical of long series of visitors who paid homage to Olympia. Even those who were least in sympathy with the old spirit of the festival could still feel that the place was representative and unique. According to Cedrenus, a Greek writer of the 11th century (Σύνοψις Ἱστοριῶν, i. 326), the Olympian festival ceased to be held after 393 A.D., the first year of the 293d Olympiad. The list of Olympian victors, which begins in 776 B.C. with Corœbus of Elis, closes with the name of an Armenian, Varastad, who is said to have belonged to the race of the Arsacidæ. In the 5th century the desolation of Olympia had set in. The chryselephantine statue of the Olympian Zeus, by Phidias, was carried to Constantinople, and perished in a great fire, 476 A.D. The Olympian temple of Zeus is said to have been destroyed, either by the Goths or by Christian zeal, in the reign of Theodosius II. (402-450 A.D.).

The German excavations at Olympia were begun in 1875. After six campaigns, of which the first five lasted from September to June, they were completed on the 20th of March 1881. The result of these six years' labours was, first, to strip off a thick covering of earth from the *Altis*, the consecrated precinct of the Olympian Zeus. This covering had been formed, during some twelve centuries, partly by clay swept down from the Cronion, partly by deposit from the overflowings of the Cladeus. The task presented to the German explorers may be judged by the fact that the coating of earth over the Altis had an average depth of no less than five metres.

Their work could not, however, be restricted to the Altis. It was necessary to dig beyond it, especially on the west, the south, and the east, where several ancient buildings existed, not included within the sacred precinct itself. The complexity of the task was further increased by the fact that in many places early Greek work had later Greek on top of it, or late Greek work had been overlaid with Roman. In a concise survey of the results obtained, it will be best to begin with the remains external to the precinct of Zeus.[1]

I.—Remains outside the Altis.

A. *West Side.*—The materials and the technical character of the wall bounding the Altis on the west are the same as those which belong to the western portion of the south Altis wall. Both belong to the earlier part of the Macedonian age, and to a time at which the Altis received its largest traceable extension to west, north-west, and south-west. In the west wall were two gates, one at its northern and the other at its southern extremity. Each gate was πρόστυλος, having before it on the west a colonnade consisting of a double row of four columns. A third and smaller gate, at about the middle point of the west wall, and nearly opposite the Pelopion in the Altis, was probably of a later age.



Plan of Olympia.

West of the west Altis wall, on the strip of ground between the Altis and the river Cladeus (of which the course is roughly parallel to the west Altis wall), the following buildings were traced. The order in which they are placed here is that in which they succeed each other from north to south.

1. Just outside the Altis at its north-west corner was a *Gymnasium.* A large open space, not regularly rectangular, was enclosed on two sides—possibly on three—by Doric colonnades. On the south it was bordered by a portico with a single row of columns in front; on the east by a longer portico, with a similar colonnade in front, and a second row, parallel to the first, traversing the interior of the portico itself. At the south-east corner of the gymnasium, in the angle between the south and the east portico, was a Corinthian doorway, which a double row of columns divided into three passages. Immediately to the east of this doorway was the gate giving access to the Altis at its north-west corner. The gymnasium was used for practice in the first four exercises of the pentathlon—leaping, quoit-throwing, javelin-throwing, running. The great length of the east portico is thus explained.

2. Immediately adjoining the gymnasium on the south was a *Palæstra*, the place of exercise for wrestlers and boxers. It was in the form of a square, of which each side was about 64 metres long, enclosing an inner building surrounded by a Doric colonnade. Facing this inner building on north, east, and west were rooms of different sizes, to which doors or colonnades gave access. The chief entrances to the palæstra were at south-west and south-east, separated by a long Ionic porch which extended along the south side.

3. Near the palæstra on the south a Byzantine church forms the central point in a complex group of remains. (*a*) The church itself occupies the site of an older brick building, which is perhaps a remnant of the "workshop of Phidias" seen by Pausanias. (*b*) North of the church is a square fountain-house, of the Hellenic age. (*c*) West of this is a small circular structure, enclosed by square walls. An altar found (*in situ*) on the south side of the circular enclosure shows by an inscription that this was the *Heroon*, where worship of the heroes was practised down to a late period. (*d*) East of the fountain-house stood a large building, of Roman age at latest, arranged round an inner hall with colonnades. Its particular destination is uncertain. (*e*) So, too, is that of a long and narrow building on the south of the Byzantine church. It may have been the priests' house mentioned by Pausanias, or it may have been occupied by the φαιδρύνται, those alleged "descendants of Phidias" (Paus. v. 14) whose hereditary privilege it was to keep the statue of Zeus clean. The so-called "workshop of Phidias" (see *a*) evidently owed its preservation to the fact that it continued to be used for actual work, and the adjacent building would have been a convenient lodging for the artists.

4. South of the group described above occur the remains of a large building, dating from the late Hellenic or early Macedonian age. It is an oblong, of which the north and south sides measure about 80 metres, the east and west about 73. Its orientation differs from that of all the other buildings above mentioned, being not from north to south, but from west-south-west to east-north-east; and there are signs that it was built before the west Altis wall. Externally it is an Ionic peripteros, enclosing suites of rooms, large and small, grouped round a small interior Doric peristyle. In Roman times it was altered in such a way as to distribute the rooms into (apparently) four quarters, each having an atrium with six or four columns. The most probable conjecture is that it was used as a lodging for distinguished visitors during the games, such as the heads of the special missions from the various Greek cities (ἀρχιθέωροι), or Roman officials. Traces existing within the exterior porticos on north, west, and east indicate much carriage traffic.

B. *South Side.*—Although the limits of the Altis on the south (*i.e.*, on the side towards the Alpheus) can be traced with approximate accuracy, the precise line of the south wall becomes doubtful after we have advanced a little more than one-third of the distance from the west to the east end of the south side. The middle and eastern portions of the south side were places at which architectural changes, large or small, were numerous down to the latest times, and where the older buildings met with scant mercy. The westernmost and best-defined part of the south-wall line is, as already stated, coeval with the west wall, belonging to the early Macedonian age.

1. The *Council Hall* (βουλευτήριον, Paus v. 23) was just outside the Altis, nearly at the middle of its south wall. It comprised

[1] Permission to use the accompanying plan of Olympia has kindly been given by the publisher, Herr Weidmann of Berlin.

two separate Doric buildings of identical form, viz., oblong, having a single row of columns dividing the length into two naves, and terminating to the east in a semicircular apse. The orientation of each was from west-south-west to east-north-east, one being south-south-east of the other. In the space between stood a small square building. In front, on the east, was a portico extending along the front of all three buildings; and east of this again a large trapeze-shaped vestibule or fore-hall, enclosed by a colonnade. This bouleuterion would have been available on all occasions when Olympia became the scene of conference or debate between the representatives of different states,—whether the subject was properly political, as concerning the amphictyonic treaties, or related more directly to the administration of the sanctuary and festival. Two smaller Hellenic buildings stood immediately west of the bouleuterion. The more northerly of the two opened on the Altis. Their purpose is uncertain.

2. Close to the bouleuterion on the south, and running parallel with it from south-west by west to north-east by east, was the *South Portico*, a late but handsome structure, closed on the north side, open on the south and at the east and west ends. The external colonnade (on south, east, and west) was Doric; the interior row of columns Corinthian. It was used as a promenade, and as a place from which to view the festal processions as they passed towards the Altis.

3. East of the bouleuterion was a gateway of Roman age, with triple entrance, the central being the widest, opening on the Altis from the south. North of this gateway, but at a somewhat greater depth, traces of a pavement were found in the Altis. This was manifestly the gateway by which the sacred processions entered the Altis in Roman times. The older processional route, however, probably struck the south boundary of the Altis at a point somewhat to the west of the Roman gate, proceeding past the front of the bouleuterion and the eastern end of the south portico.

C. *East Side*.—The line of the east wall, running due north and south, can be traced from the north-east corner of the Altis down about three-fifths of the east side, when it breaks off at the remains known as "Nero's house." These are the first which claim attention on the east side.

1. Pausanias mentions a building called the *Leonidaion*, erected by the Elean Leonidas "*outside* the Altis, and near the Processional Gate." This Leonidaion was the point from which he set out on many of his walks in the Altis. Its original form is traceable in Hellenic remains at the south-east angle of the Altis, which show that the Leonidaion—an oblong structure with colonnade on north, west, and south—stood *within* the Altis. But the Greek Leonidaion was afterwards absorbed into a Roman house which projected beyond the Altis on the east, the south part of the east Altis wall being destroyed to admit of this. A piece of leaden water-pipe found in the house bears NER. AVG. Only a Roman master could have dealt thus with the Altis, and with a building which, like the Leonidaion, stood within its sacred precinct. It cannot be doubted that the Roman house—from which three doors gave access to the Altis—was that occupied by Nero when he visited Olympia. Later Roman hands again enlarged and altered the building, which may perhaps have been used for the reception of Roman governors. But Pausanias, who speaks only of a Leonidaion, shows that the old Greek name was retained, even when the building of Nero's time had placed the new Leonidaion beyond the limits of the Altis.

2. Following northwards the line of the east wall, we reach at the north-east corner of the Altis the entrance to the *Stadion*, which extends east of the Altis in a direction from west-south-west to east-north-east. The apparently strange and inconvenient position of the Stadion relatively to the Altis was due simply to the necessity of obeying the conditions of the ground, here determined by the curve of the lower slopes which bound the valley on the north. The German explorers excavated the Stadion so far as was necessary for the ascertainment of all essential points. Weak walls had originally been built on west, east, and south, the north boundary being formed by the natural slope of the hill. The walls were afterwards thickened and raised. The space thus defined was a large oblong, about 214 metres in length by 32 in breadth. There were no artificial seats. It is computed that from 40,000 to 45,000 spectators could have found sitting-room, though it is hardly probable that such a number was ever reached. The exact length of the Stadion itself—which was primarily the course for the foot-race—was 192·27 metres,—an important result, as it determines the Olympian foot to be 0·3204 metre. In the Heraion at Olympia, it may be remarked, the unit adopted was not this Olympian foot, but an older one of 0·297 metre. The starting-point and the goal in the Stadion were marked by limestone thresholds. Provision for drainage was made by a channel running round the enclosure. The Stadion was used not only for foot-races but for boxing, wrestling, leaping, quoit-throwing, and javelin-throwing.

The entrance to the Stadion from the north-east corner of the Altis was a privileged one, reserved for the judges of the games, the competitors, and the heralds. Its form was that of a vaulted tunnel, 100 Olympian feet in length. Dating from about 350-300 B.C., it is one of the oldest examples of vaulted work in cut stone. To the west was a vestibule, from which the Altis was entered by a handsome gateway.

3. The *Hippodrome*, in which the chariot-races and horse-races were held, can no longer be accurately traced. The overflowings of the Alpheus have washed away all certain indications of its limits. But it is clear that it extended south and south-east of the Stadion, and roughly parallel with it, though stretching far beyond it to the east. From the state of the ground the German explorers inferred that the length of the hippodrome was 770 metres or 4 Olympic stadia.

D. *North Side*.—If the northern limit of the Altis, like the west, south, and east, had been traced by a boundary wall, this would have had the effect of excluding from the precinct a spot so sacred as the Cronion, the hill inseparably associated with the oldest worship of Zeus at Olympia. It seems therefore unlikely that any such northern boundary wall ever existed. But the line which such a boundary would have followed is partly represented by the remains of a wall running from east to west immediately north of the treasure-houses (see below), which it was designed to protect against the descent of earth from the Cronion just above. This was the wall along which, about 157 A.D., the main water-channel constructed by Herodes Atticus was carried.

Having now surveyed the chief remains external to the sacred precinct on west, south, east, and north, we proceed to notice those which have been traced within it.

II.—Remains within the Altis.

The form of the Altis, as indicated by the existing traces, is not regularly rectangular. The length of the west side, where the line of direction is from south-south-east to north-north-west, is about 195 metres. The south side, running nearly due east and west, is about equally long, if measured from the end of the west wall to the point which the east wall would touch when produced due south in a straight line from the place at which it was demolished to make way for "Nero's house." The east side, measured to a point just behind the treasure-houses, is the shortest, about 180 metres. The north side is the longest. A line drawn eastward behind the treasure-houses, from the Prytaneion at the north-west angle, would give about 250 metres.

The remains or sites within the Altis may conveniently be classed in three main groups, viz.—(A) the chief centres of religious worship; (B) votive buildings; (C) buildings, &c., connected with the administration of Olympia or the reception of visitors.

A. *Chief Centres of Religious Worship*.—1. The earliest Hellenic phase of the sanctuary, when a pre-Hellenic worship of Zeus was combined with a cult of the hero Pelops, is recalled by the *Altar of Zeus*. This, the central object of the older temenos, stood a little east of the Pelopion, and after the Altis had been enlarged was still nearly at its centre. The basis was of elliptic form, the length of the lozenge being directed from south-south-west to north-north-east, in such a manner that the axis would pass through the Cronion. The upper structure imposed on this basis was in two tiers, and also, probably, lozenge-shaped. This was the famous "ash-altar" at which the Iamidæ, the hereditary gens of μάντεις, practised those rites of divination by fire (μαντικὴ δι' ἐμπύρων) in virtue of which more especially Olympia is saluted by Pindar as "mistress of truth" (δέσποιν' ἀλαθείας). The steps by which the priests mounted the altar seem to have been at north and south.

2. The *Pelopion*, to the west of the Altar of Zeus, was a small precinct in which, from the time when Pisa was founded by the Achæans, sacrifices were offered to the Achæan ἥρως Pelops. The traces agree with the account of Pausanias. Walls, inclined to each other at obtuse angles, enclosed a plot of ground having in the middle a low tumulus of elliptic form, about 35 metres from east to west by 20 from north to south. A Doric propylaion with three doors gave access on the south-west side.

The three temples of the Altis were those of Zeus, Hera, and the Mother of the gods. All were Doric. All, too, were completely surrounded by a colonnade, *i.e.*, were "peripteral."

3. The *Temple of Zeus*, south of the Pelopion, stood on a high substructure with three steps. The colonnades at the east and west side were of six columns each; those at the north and south sides (counting the corner columns again) of thirteen each. The cella had a prodomos on the east and an opisthodomos on the west. The cella itself was divided longitudinally (*i.e.*, from east to west) into three partitions by a double row of columns. The central partition, which was the widest, consisted of three sections. The west section was shut off; it contained the throne and image of the Olympian Zeus. The middle section, next to the east, contained a table and stelæ. Here, probably, the wreaths were presented to the victors. The third or easternmost section, which had side porticos, was open to the public. This temple was most richly adorned with statues and reliefs. On the east front Pæonius had represented in twenty-one colossal figures the moment before the contest between Œnomaus and Pelops. The west front exhibited the fight of the

Lapithæ and Centaurs, and was connected with the name of Alcamenes. The Twelve Labours of Heracles were depicted on the metopes of the prodomos and opisthodomos; and of these reliefs much the greater part was found,—enough to determine with certainty all the essential features of the composition. It was near this temple, at a point about 35 metres east-south-east from the south-east angle, that the explorers found the fragment of a flying goddess of victory—the Nike of Pæonius.

4. The *Temple of Hera* (Heraion), north of the Pelopion, was raised on two steps. It was originally built as a temple *in antis*, and afterwards converted into a peripteros, having colonnades of six columns each at east and west, and of sixteen each (counting the corner columns again) at north and south. It was smaller than the temple of Zeus, and, while resembling it in general plan, differed from it by its singular length relatively to its breadth. When Pausanias saw it, one of the two columns of the opisthodomos (at the west end of the cella) was of wood; and for a long period all the columns of this temple had probably been of the same material. A good deal of patch-work in the restoration of particular parts seems to have been done at various periods. The cella—divided, like that of Zeus, into three partitions by a double row of columns—had four "tongue-walls," or small screens, projecting at right angles from its north wall, and as many from the south wall. Five niches were thus formed on the north side and five on the south. In the third niche from the east, on the north side of the cella, was found one of the greatest of all the treasures which rewarded the German explorers,—the Hermes of Praxiteles (1878).

5. The *Temple of the Mother of the Gods* (Metroon) was again considerably smaller than the Heraion. It stood to the east of the latter, and had a different orientation, viz., not west to east, but west-north-west to east-south-east. It was raised on three steps, and had a peripteros of six columns (east and west) by eleven (north and south), having thus a slightly smaller length relatively to its breadth than either of the other two temples. Here also the cella had prodomos and opisthodomos. The adornment and painting of this temple had once been very rich and varied. There are indications that in Roman times it underwent a restoration, conducted, apparently, with little taste or skill.

B. *Votive Edifices.*—Under this head are placed buildings erected, either by states or by individuals, as offerings to the Olympian god.

1. The twelve *Treasure-houses* on the north side of the Altis, immediately under the Cronion, belong to this class. We have seen that on the north side the limit of the Altis does not seem to have been defined by a wall, as on the other three sides. Here, then, we cannot distinguish with the same precision between objects within or without the precinct. The row of treasure-houses is, however, so situated that they are most naturally regarded as standing *within* the Altis, with a single exception. This is the easternmost of the twelve, the treasure-house dedicated by the state of Gela, which projected on the east beyond the line of the east Altis wall. It was evidently the oldest of the series. Originally planned as a small Doric temple *in antis*, of which the longer sides were the north and south, it was afterwards adorned on the south side with a colonnade, having six columns in front. Doric cut stone-work, overlaid with coloured terra-cotta plates, occurred here, as in monuments found at Gela itself, at Selinus, and elsewhere in Sicily.

The same general character—that of a Doric temple *in antis*, facing south—is traceable in all its younger neighbours on the west. In the cases of six of these the fragments are sufficient to aid a reconstruction. Two—viz., the 2d and 3d counting from the west—had been dismantled at an early date, and their site was traversed by a roadway winding upward towards the Cronion. This roadway seems to have been older at least than 157 A.D., since it caused a deflexion in the watercourse along the base of the Cronion constructed by Herodes Atticus. Pausanias, therefore, would not have seen treasure-houses Nos. 2 and 3. This explains the fact that, though we can trace twelve, he names only ten.

As the temples of ancient Greece partly served the purposes of banks, in which precious objects could be securely deposited, so the form of a small Doric chapel was a natural one for the "treasure-house" to assume. Each of these treasure-houses was erected by a Greek state, either as a thank-offering for Olympian victories gained by its citizens, or as a general mark of homage to the Olympian Zeus. The treasure-houses were designed to contain the various ἀναθήματα or dedicated gifts (such as gold and silver plate, &c.), in which the wealth of the sanctuary partly consisted. The temple inventories recently discovered at Delos illustrate the great quantity of such possessions which were apt to accumulate at a shrine of Panhellenic celebrity. Taken in order from the west, the treasure-houses were founded by the following states:—1, Sicyon; 2, 3, unknown; 4, Syracuse (referred by Pausanias to Carthage); 5, Epidamnus; 6, Byzantium; 7, Sybaris; 8, Cyrene; 9, Selinus; 10, Metapontum; 11, Megara; 12, Gela. It is interesting to remark how this list represents the Greek colonies, from Libya to Sicily, from the Euxine to the Adriatic. Greece proper, on the other hand, is represented only by Megara and Sicyon. The dates of the foundations cannot be fixed.

2. The *Philippeion* stood near the north-west corner of the Altis, a short space west-south-west of the Heraion. It was dedicated by Philip of Macedon, after his victory at Chæronea (338 B.C.). As a thank-offering for the overthrow of Greek freedom, it might seem strangely placed in the Olympian Altis. But it is, in fact, only another illustration of the manner in which Philip's position and power enabled him to place a decent disguise on the real nature of the change. Without risking any revolt of Hellenic feeling, the new "captain-general" of Greece could erect a monument of his triumph in the very heart of the Panhellenic sanctuary. The building consisted of a circular Ionic colonnade (of eighteen columns), about 15 metres in diameter, raised on three steps, and enclosing a small circular cella, probably adorned with fourteen Corinthian half-columns.

3. The *Exedra of Herodes Atticus* stood at the north limit of the Altis, close to the north-east angle of the Heraion, and immediately west of the westernmost treasure-house (that of Sicyon). It consisted of a half-dome of brick, 16·6 metres in diameter, with south-south-west aspect. Under the half-dome were placed twenty-one marble statues, representing the family of Antoninus Pius, of Marcus Aurelius, and of the founder, Herodes Atticus. In front of the half-dome on the south, and extending slightly beyond it, was a basin of water for drinking, 22 metres long. The ends of the basin at north-north-west and south-south-east were adorned by very small open temples, each with a circular colonnade of eight pillars. A marble bull, in front of the basin, bore an inscription saying that Herodes dedicates the whole to Zeus, in the name of his wife, Annia Regilla. The exedra must have been seen by Pausanias, but he does not mention it.

C. It remains to notice those features of the Altis which were connected with the management of the sanctuary or with the accommodation of its guests.

1. Olympia, besides its religious character, originally possessed also a political character, as the centre of an amphictyony. It was, in fact, a sacred πόλις. We have seen that it had a bouleuterion for purposes of public debate or conference. So also it was needful that, like a Greek city, it should have a public hearth or prytaneion, where fire should always burn on the altar of the Olympian Hestia, and where the controllers of Olympia should exercise public hospitality. The *Prytaneion* was at the north-west corner of the Altis, in such a position that its south-east angle was close to the north-west angle of the Heraion. It was apparently a square building, of which each side measured 100 Olympian feet, with a south-west aspect. It contained a chapel of Hestia at the front or south-west side, before which a portico was afterwards built. The dining-hall was at the back (north-east), the kitchen on the north-west side. On the same side with the kitchen, and also on the opposite side (south-east), there were some smaller rooms.

2. The *Porch of Echo*, also called the "Painted Porch" (στοὰ ποικίλη), extended to a length of 96 metres along the east Altis wall. Raised on three steps, and formed by a single Doric colonnade, open towards the Altis, it afforded a place from which spectators could conveniently view the passage of processions and the sacrifices at the great altar of Zeus.

3. Before the Porch of Echo, and east of the Altar of Zeus, was the *Proedria*, a structure 20 metres long, containing places of honour for officials and visitors of distinction. A flight of steps, curved inwards in a semicircle, gave access from the west. At either end of the Proedria (north and south) stood a colossal Ionic column. These columns, as the inscriptions show, once supported statues of Ptolemy and Berenice.

4. The *Agora* was the name given to that part of the Altis which had the Porch of Echo and Proedria on the east, the Altar of Zeus on the west, the Metroon on the north, and the precinct of the Temple of Zeus on the south-west. In this part stood the altars of Zeus Agoraios and Artemis Agoraia.

5. The *Zanes* (Ζᾶνες) were brazen images of Zeus, the cost of making which was defrayed by the fines exacted from competitors who had infringed the rules of the contests at Olympia. These images stood at the northern side of the Agora, in a row, which extended from the north-east angle of the Metroon to the gate of the private entrance from the Altis into the stadion. Sixteen pedestals were here discovered *in situ*. A lesson of loyalty was thus impressed on aspirants to renown by the last objects which met their eyes as they passed from the sacred enclosure to the scene of their trial.

6. *Arrangements for Water-supply.*—A copious supply of water was required for the service of the altars and temples, for the private dwellings of priests and officials, for the use of the gymnasium, palæstra, &c., and for the thermæ which arose in Roman times. In the Hellenic age the water was derived wholly from the Cladeus and from the small lateral tributaries of its valley. A basin, to serve as a chief reservoir, was built at the north-west corner of the Altis; and a supplementary reservoir was afterwards constructed a little to the north-east of this, on the slope of the Cronion. A new source of supply was for the first time made available by Herodes Atticus, c. 157 A.D. At a short distance

east of Olympia, near the village of Miraka, small streams flow
from comparatively high ground through the side-valleys which
descend towards the right or northern bank of the Alpheus. From
these side-valleys water was now conducted to Olympia, entering
the Altis at its north-east corner by an arched canal which passed
behind the treasure-houses to the reservoir at the back of the
exedra. The large basin of drinking-water in front of the exedra
was fed thence, and served to associate the name of Herodes with
a benefit of the highest practical value. Olympia further possessed
several fountains, enclosed by round or square walls, chiefly in
connexion with the buildings outside the Altis. The drainage of
the Altis followed two main lines. One, for the west part, passed
from the south-west angle of the Heraion to the south portico
outside the south Altis wall. The other, which served for the treasure-houses, passed in front of the Porch of Echo parallel with the
line of the east Altis wall. The whole subject of the water-works
of Olympia was exhaustively investigated by Herr Gräber, and has
been explained by him in vol. v. of the *Excavations* pp. 26 *sq.*

Such, in brief outline, are the more important results of the German exploration of Olympia, an enterprise alike honourable to the Government which undertook it and to the eminent men by whom it was conducted. The work of excavation was from the outset guided by scientific knowledge, and the results were at no point confused or obscured by rash and unsound theories. The general outcome of the undertaking is certainly greater than could have reasonably been anticipated at its commencement. In the Olympia seen by Pausanias there was, of course, very much of which not the slightest trace has been found,—such, for instance, as the temples of Eileithyia, of Aphrodite Urania, and of Demeter Chameune. In regard to particular works of art, many hopes of discovery have been disappointed, nor can "the survival of the fittest" be always acknowledged in the salvage from so many centuries of ruin. On the other hand, the German campaigns had their welcome surprises and their strokes of good fortune, such as the finding of the Hermes and the Nice. Above all, they have their reward in this, that the topography of Olympia is now thoroughly ascertained. We now know with certainty the exact position of the principal buildings, the plan of the Altis and its relation to its whole environment, and all the main local conditions of the festival. In reading an Olympian ode of Pindar, the modern student can now call up the scene with adequate fulness of detail. Precious as are the particular works of ancient art which have been discovered, and valuable as are the results of the study of art and architecture, the largest gain of all consists in the vivid and suggestive light thus shed on a great centre of Hellenic history and life. (R. C. J.)

OLYMPIAS, the ambitious and energetic wife of Philip II., king of Macedonia, and the mother of Alexander III., commonly called The Great, was daughter of Neoptolemus I., king of Epirus, who claimed to be descended from Pyrrhus, son of Achilles. Plutarch tells us that it was while being initiated in the Samothracian mysteries, in which she was an enthusiastic participant, that Philip, still very young, fell in love with her. The marriage took place in 359 B.C., shortly after his accession, and Alexander was born in 356. There was also a daughter, named Cleopatra. The fickleness of Philip and the vehement and jealous temper of Olympias led to a growing estrangement, which became complete when Philip married a second wife, Cleopatra, in 337. Alexander, who strongly sided with his mother, withdrew, along with her, into Epirus, whence they both returned in the following year, after the assassination of Philip, which Olympias is said to have countenanced. During the absence of Alexander, with whom she had regular correspondence on public as well as domestic affairs, she had great influence in Macedonia, and by her arrogance and ambition gave great trouble to Antipater,—so great, indeed, that on the death of her son (323) she found it prudent to withdraw into Epirus. Here she remained until 317, when, allying herself with Polysperchon, by whom her old enemy had been succeeded in 319, she took the field with an Epirote army; the opposing troops at once declared in her favour, and for a short period Olympias was mistress of Macedonia. Cassander, Antipater's son, speedily, however, returned from the Peloponnesus, and, after an obstinate siege, compelled the surrender of Pydna, where she had taken refuge. One of the terms of the capitulation had been that her life should be spared; but this did not protect her against trial for numerous and cruel executions (including that of Nicanor, Cassander's brother) of which she had been guilty during her short lease of power. Condemned without a hearing, she was put to death tumultuously by the friends of those whom she had slain, and Cassander is said to have denied her remains the rites of burial (316).

OLYMPUS, the name of many mountains in Greece and Asia Minor, and of the fabled home of the gods, and also a city name and a personal name.

I. Of the mountains bearing the name the most famous is the lofty ridge on the borders of Thessaly and Macedonia. The river Peneus, which drains Thessaly, finds its way to the sea through the great gorge of Tempe, which is close below the south-eastern end of Olympus and separates it from Mount Ossa. The highest peak of Olympus is over 9000 feet high; it is covered with snow for great part of the year. Olympus is a mountain of massive appearance, in many places rising in tremendous precipices broken by vast ravines, above which is the broad summit. The lower parts are densely wooded; the summit is naked rock. Homer calls the mountain ἀγάννιφος, μακρός, πολυδειράς; the epithets νιφοείς, πολύδενδρος, *frondosus*, and *opacus* are used by other poets. The modern name is Ἔλυμπο, a dialectic form of the ancient word.

The peak of Mount Lycæus in the south-west of Arcadia was called Olympus. East of Olympia, on the north bank of the Alpheus, was a hill bearing this name; beside Sellasia in Laconia another. The name was even commoner in Asia Minor: a lofty chain in Mysia (Keshish Dagh), a ridge east of Smyrna (Nif Dagh), other mountains in Lycia, in Galatia, in Cilicia, in Cyprus, &c., were all called Olympus.

II. A lofty peak, rising high above the clouds of the lower atmosphere into the clear ether, seemed to be the chosen seat of the deity. Homer distinguishes between Olympus, which is the mountain, and the heaven or ether; but later poets use the terms as practically equivalent. In the elaborate mythology of Greek literature Olympus was the common home of the multitude of gods. Each deity had his special haunts, but all had a residence at the court of Zeus on Olympus; here were held the assemblies and the common feasts of the gods.

III. There was a city in Lycia named Olympus; it was a bishopric in the Byzantine time.

IV. A semi-historical musician, named Olympus, was connected with the development of flute music about 700 B.C. It is probable that he introduced the double flute, and increased the number of holes in the instrument and the tones of which it was capable: on the right flute were three holes for the low notes, on the left four for the high notes. He also brought into use compositions for the flute without words (κρούματα). It is said that he was an elegiac poet, but this is apparently a misconception. It is difficult to say whether Olympus is an actual historical person, or whether he merely represents in an individualized form the influence which Phrygian music, used in the Phrygian religion, began to exert on the Ionian cities about 700 B.C. The growth of intercourse between Phrygia and Ionia at this time is certain (see PHRYGIA). In any case, the musical innovations associated with the name of Olympus were the beginning of a richer and more

varied school of lyric poetry, as well as of music, in the Greek world.

On the musician see, besides the general works on Greek literature, Ritschl, "Olympos der Aulet," in *Opusc.*, i.; Flach, *Gesch. d. griech. Lyrik*, 1883; Westphal, *Metrik*, &c.

OLYNTHUS was an important city of Chalcidice (see vol. xv. p. 137), situated in a fertile plain at the head of the Toronaic gulf between the peninsulas of Sithonia and Pallene, at some little distance from the sea, and about 60 stadia from Potidæa. The district belonged originally to a Thracian people, the Bottiæi; and it is said that it was given over to the Greek colonists of Chalcidice at the Persian invasion. It fell under Athenian influence during the 5th century, but regained its freedom during the invasion of Brasidas (424 B.C.). It became the head of a great confederacy, and its power excited the jealousy of Sparta. A war broke out 383-379, and Olynthus was compelled to become a member of the Spartan confederacy. No long time afterwards the Athenians made themselves masters of several towns which had previously been under the influence of Olynthus, and then a new and more dangerous enemy appeared on the northern frontier. Philip of Macedon found the city his most powerful rival, and directed all his strength against it. The Athenians made an alliance with Olynthus, but did not give any active aid, though Demosthenes tried hard to induce them to oppose Philip before he grew too strong. The famous series of Olynthiac orations was delivered by him at this crisis. After a long siege the city was captured by treachery in 347 B.C.; it was razed to the ground, and the people sold as slaves.

OMAHA, the largest city in Nebraska, U.S., is situated on the west bank of the Missouri, 600 miles from its confluence with the Mississippi, in 41° 15' 43" N. lat. and 95° 55' 47" W. long. (time $1^h\ 16^m$ after that of Washington). The lower part, situated mainly on a terrace, is principally devoted to business; the upper part, on the bluffs, to the finer residences, parks, and churches. It was founded in 1854, and in 1855 it became the capital of Nebraska Territory, when its inhabitants numbered little over 100; Lincoln, however, is the capital of the State. The population (1883 in 1860, 16,083 in 1870) was 30,518 in 1880, and in 1883 had risen to 49,710, its present growth surpassing that of any former period. Omaha contains the most extensive smelting and refining works in the Union. The number of men employed is 300, and the production of metals in 1882 was—lead, 43,711,921 lb; gold, 16,272 oz. fine; silver, 4,853,851 oz. fine; sulphate of copper, 152,041 lb. Other manufactures amount to over $7,000,000 annually. The educational institutions include Creighton College, Brownell Hall for young ladies, a medical college, and a business college. The high school building, erected at a cost of $250,000, is one of the finest in the country. There are besides ten free schoolhouses, containing seventy-four schoolrooms. Among the public buildings are the post-office and court-house, an opera-house seating 1700 people, many hotels, and numerous churches. The streets are wide and cross at right angles, and the business portions are in process of being paved. The city is lighted by gas and the electric light. Street railways penetrate in all directions. Omaha is also an important railroad centre.

OMAN, or 'OMÁN. See ARABIA.

'OMAR. See MOHAMMEDANISM, vol. xvi. pp. 563, 574.

'OMAR KHAYYÁM. The great Persian mathematician, astronomer, freethinker, and epigrammatist, Ghiyáth-uddín Abulfath 'Omar bin Ibráhím al-Khayyámí, who derived the epithet Khayyám (the tentmaker) most likely from his father's trade, was born in or close by Níshápúr, and is stated to have died there in 517 A.H. (1123 A.D.). This date is accepted by most Eastern and Western writers, but the renowned vizier of the Seljúk sultáns Alp Arslan and Maliksháh, Nizám-ulmulk of Tús, whose birth is fixed in 408 A.H. (1017 A.D.), expressly states in one of his writings that 'Omar was of the same age as himself, and attended with him the lectures of the imám Muwaffak in the college of Níshápúr. However that may be, there cannot be the slightest doubt that at an early age 'Omar entered into a close friendship both with Nizám-ulmulk and his schoolfellow Hasan ibn Ṣabbáḥ, who founded afterwards the terrible sect of the Isma'ílís or Assassins. The three friends pledged themselves by a solemn promise that he who should first gain an influential position in the world would lend a helping hand to the other two and promote their success in life. When Nizám-ulmulk was raised to the rank of vizier by Alp Arslan (1063-1073 A.D.) he remembered this covenant and bestowed upon Hasan ibn Ṣabbáḥ the dignity of a chamberlain, whilst offering a similar court office to 'Omar Khayyám. But the latter contented himself with an annual stipend which would enable him to devote all his time to his favourite studies of mathematics and astronomy, and he soon proved his gratitude for the liberality of his patron and friend by the publication of his standard work on algebra, written in Arabic. This and other treatises of a similar character—for instance, on the extraction of cube roots and on the explanation of difficult definitions in Euclid—raised him at once to the foremost rank among the mathematicians of that age, and induced Sultán Malikshâh to summon him in 467 A.H. (1074 A.D.) to institute astronomical observations on a larger scale, and to aid him in his great enterprise of a thorough reform of the calendar. A twofold fruit resulted from 'Omar's elaborate research in the sultan's observatory,—a revised edition of the Zíj or astronomical tables, and the introduction of the Ta'ríkh-i-Malikshâhí or Jalálí, that is, the so-called Jalálian or Seljúk era, which commences in 471 A.H. (1079 A.D., 15th March).

Great, however, as 'Omar's scientific fame has always been throughout the East, it is nearly eclipsed by his still greater poetical renown, which he owes to his *rubá'is* or quatrains, a collection of about 500 epigrams, unequalled by any of his predecessors or followers. The peculiar form of the rubá'í—viz., four lines, the first, second, and fourth of which have the same rhyme, while the third usually (but not always) remains rhymeless—was first successfully introduced into Persian literature as the exclusive vehicle for subtle thoughts on the various topics of Súfic mysticism by the sheikh Abú Sa'íd bin Abulkhair,[1] but 'Omar differs in its treatment considerably from Abú Sa'íd. Although some of his quatrains are purely mystic and pantheistic, most of them bear quite another stamp; they are the breviary of a radical freethinker, who protests in the most forcible manner both against the narrowness, bigotry, and uncompromising austerity of the orthodox ulemá and the eccentricity, hypocrisy, and wild ravings of advanced Súfís, whom he successfully combats with their own weapons, using the whole mystic terminology simply to ridicule mysticism itself. There is in this respect a great resemblance between him and Háfiz, but 'Omar is decidedly superior, not so much on account of his priority as for his more concise, more simple, and yet infinitely more energetic style. He has often been called the Voltaire of the East, and cried down as materialist and atheist. As far as purity of diction, fine wit, crushing satire against a debased and ignorant clergy, and a general sympathy with suffering humanity are concerned, 'Omar certainly reminds us of the great Frenchman; but there the comparison ceases. Voltaire never wrote anything equal to

[1] Died Jan. 1049. Comp. Ethé's edition of his rubá'ís in *Sitzungsberichte der bayr. Akademie*, 1875, pp. 145 sq., and 1878, pp. 38 sq.

'Omar's fascinating rhapsodies in praise of wine, love, and all earthly joys, to the fervent effusions of his heart so full of the most tender feelings and affections, and his passionate denunciations of a malevolent and inexorable fate which dooms to slow decay or sudden death and to eternal oblivion all that is great, good, and beautiful in this world. There is a touch of Byron, Swinburne, and even of Schopenhauer in many of his rubá'is, which clearly proves that the modern pessimist is by no means a novel creature in the realm of philosophic thought and poetical imagination.

The Leyden copy of 'Omar Khayyám's work on algebra was noticed as far back as 1742 by Gerald Meerman in the preface to his *Specimen calculi fluxionalis*; further notices of the same work by Sédillot appeared in the *Nouv. Jour. As.*, 1834, and in vol. xiii. of the *Notices et Extraits des MSS. de la Bibl. roy.* The complete text, together with a French translation (on the basis of the Leyden and Paris copies, the latter first discovered by M. Libri, see his *Histoire des sciences mathématiques en Italie*, i. 300), was edited by F. Woepcke, *L'algèbre d'Omar Alkhayyâmi*, Paris, 1851. Articles on 'Omar's life and works are found in Reinaud's *Géographie d'Aboulféda*, pref., p. 101; *Notices et Extraits*, ix. 143 *sq.*; Garcin de Tassy, *Note sur les Rubâ'iyât de 'Omar Khaïyâm*, Paris, 1857; and Rieu, *Cat. Pers. MSS. in the Br. Mus.*, ii. p. 546. The quatrains have been edited at Calcutta, 1836, and Teheran, 1857 and 1862; text and French translation by J. B. Nicolas, Paris, 1867 (very incorrect and misleading); a portion of the same, rendered in English verse, by E. Fitzgerald, London, 1859, 1872, and 1879. A new English version was published in Trübner's "Oriental Series," 1882, by E. H. Whinfield, and the first critical edition of the text, with translation, by the same, 1883. (H. E.)

OMAYYADS. See MOHAMMEDANISM.

OMEN. See AUGURS, DIVINATION, and MAGIC.

OMSK, the chief town of the government of Akmolinsk and capital of western Siberia, stands at the junction of the Om with the Irtish, on the great highway of Siberia, 1795 miles east of Moscow. Distant as it is from the great line of steamboat communication leading to Tomsk, the true commercial capital of western Siberia, Omsk has a purely administrative importance; its "fortress," or old earthwork, is now almost entirely abandoned. The town, situated in a wide steppe, broken only by the gently-sloping hill occupied by the fort, is almost entirely of wood. It has a military school, a lyceum, several lower schools, and a small public library. A "West Siberian branch of the Russian Geographical Society," opened in 1877, issues valuable publications. Its industries (candlemaking, tanning, and the like) are insignificant; but the trade, chiefly in cattle, skins, and furs imported from the Kirghiz Steppe, and partly also in tea, is of some importance. The population, which is entirely Russian, numbers about 31,000, of whom about 5000 are military.

The "fort" of Omsk was erected in 1716 to protect the series of block-houses on the Russian frontier, and, as two lines of block-houses—that of the Ishim and that of the Irtish—met at this point, it became a military centre. In consequence of frequent incursions of the Kirghiz about the end of the last century, a stronger earthwork, with bastions and a stone gate, was erected on the right bank of the Om. From being a district town of the government of Tobolsk, Omsk became in 1839 the seat of the administration of western Siberia in anticipation of a further advance of the Russians towards the south. Since the conquest of Turkestan it has lost even this strategic importance.

ON, or HELIOPOLIS. See EGYPT, vol. vii. p. 769.

ONEGA, next to Ladoga the largest lake in Europe, having according to Strelbitskiy an area of 3763 square miles, is situated in the heart of the government of Olonetz in European Russia, and, discharging its waters by the Svir into Lake Ladoga, belongs to the system of the Neva. The lake basin lies north-west and south-east, the same direction which is common to the lakes of Finland and to the line of glacier-scoring observed in this region. A straight line drawn from the village of Lumbuzha at the head of Povyenets Bay on the north to Oshta in the south measures 145 miles, but a considerable portion of it lies across the Zaonezhe peninsula. The greatest width is 50 miles. Between the northern and southern divisions of the lake there is a considerable difference: while the latter has a comparatively regular outline, and contains hardly any islands, the former splits up into a number of inlets and is full of islands and submerged rocks. It is thus the northern division which brings the coast-line up to 860 miles and causes the navigation of the lake to be so dangerous that previous to 1874, when additional buoys and beacons were laid down, the loss of life from shipwreck was about eighty persons per annum. The north-western shore between Petrozavodsk and the mouth of the river Lumbuzha consists of dark clay slates generally in horizontal strata and broken by raised parallel bands of diorite. These bands extend far into the lake and are locally known as "hogs' backs." The eastern shore (as far as the mouth of the Andoma) is for the most part alluvial, with outcroppings of red granite and in one place (the mouth of the Pyalma) diorite and dolomite. To the south-east are sedimentary Devonian rocks, and the general level of the coast is broken by Mount Andoma and Cape Petropavlovskii (160 feet above the lake); to the south-west a quartzy sandstone (well known as a building and monumental stone in St Petersburg) forms a fairly bold rim. Onega lies 236 feet above the sea. Towards the centre of the southern section a considerable area is upwards of 165 feet deep, and at one place a depth of 738 feet has been reached. The most important affluents, the Vodka, the Andoma, and the Vuiterga, come from the east. The Kumsa, a northern tributary, is sometimes represented in maps as if it connected the lake with Lake Seg, but the latter drains to the White Sea, and proposals to restore by means of a canal the communication which formerly existed here between the Arctic and Baltic basins have not yet been carried out. Lake Onega remains free from ice for 209 days in the year (middle of May to second week of December). The water is at its lowest level in the beginning of March; by June it has risen 2 feet. A considerable population is scattered along the shores of the lake, mainly occupied in the timber trade, fisheries, and mining industries. Salmon, palya (a kind of trout), burbot, pike, perchpike, and perch are among the fish caught in the lake. Steamboats were introduced in 1832.

It is to be noted that the river Onega, which after a course of about 260 miles reaches the Gulf of Onega, an inlet of the White Sea, has no connexion with Lake Onega. At the mouth of this river (on the right bank) stands the district town and port of Onega (2275), which dates from settlements made by the people of Novgorod in the 15th century, and known in history as the Ustenskaya or Ustyanskaya volost. It has a cathedral (St Michael and the Holy Trinity), erected in 1796.

ONEIDA COMMUNITY, in Madison co., New York, is a society which has attracted wide interest on account of its pecuniary success and its peculiar religious and social principles. Its founder, organizer, and controlling mind was John H. Noyes, who in 1834, while a student and licentiate of the theological seminary of Yale College, was led by his study of the New Testament to believe that the gospel of Christ, when fully accepted, secures present salvation from sin, and that the second coming of Christ, instead of being a future event, took place, according to promise, within a single generation of His first coming. Other religious doctrines at variance with popular theology were developed by Mr Noyes, such as that God is a dual being, Father and Son; that God is in no sense responsible for the existence of evil, but that the author of evil, as the author of good, was uncreated; that, the second coming of Christ being past, we are now living in a new dispensation of grace; that personal spiritual communication with Christ and His risen church is possible, and when perfected secures salvation from all evil, including disease and death itself.

These doctrines found their practical expression in a

social system of pure communism. In the Oneida Community, founded in 1848, "not one said that aught of the things which he possessed was his own, but they had all things in common." The Community was a large family or brotherhood, numbering at one time over three hundred members, the common bond being paramount. The children were regarded as belonging primarily to the Community; and it was a favourite theory, which they made some attempts to realize, that children should be begotten and reared only under the best conditions. So far as their experiments in this direction extended, the results, they claimed, justified their theories, and they adduced in confirmation the testimony of critical observers like Professor Goldwin Smith, who wrote after a visit to the Community as follows:—

"Undeniably, they are a fine, healthy-looking, merry set of children. They are reared under conditions of exceptional advantage, which could not fail to secure health to the offspring of any but positively diseased parents. The nurseries, with everything about them, are beautiful. Large playrooms are provided for exercise in winter. The nurses are not hirelings, but members of the Community who voluntarily undertake the office. Every precaution is taken against the danger of infection. A simple and wholesome dietary is enforced, and no mother or grandmother is permitted to ruin digestion and temper by administering first a poison from the confectioner's and then another poison from the druggist's."

But, while the Oneida Communists extended the pentecostal principle to all social relations, they yet maintained strict order among themselves. The thousands of visitors who annually inspected their dwellings and factories, and admired their lawns and gardens, discovered none of the usual signs of lax social morality. Credit for this is unquestionably due in part to the strong personal influence of Mr Noyes, but credit is also due to the members for voluntarily subjecting themselves to a system of self-control in the intercourse of the sexes called "*male continence*," and to "*mutual criticism*," which last was in fact exalted into their principal means of government. The system is one of plain truth-telling, and was termed "mutual" because it was expected that all, or nearly all, would alternate as critic and subject. Sometimes persons were criticized by a standing committee selected for the purpose by the Community, sometimes by committees of their own selection, sometimes by the whole Community. The critics were expected in all cases to speak the truth without fear or favour, that the subject might see himself, whatever his faults or virtues, as others saw him.

Radical as its theories and practices were, the Oneida Community was able to conduct its experiment with much success for thirty years. About that time public opinion, aroused by the clergy of the surrounding region, demanded that its social practices should be abandoned; and this was accordingly done in 1879, under the counsel of its founder and president, Mr Noyes, who had many times previously expressed his willingness to conform to the wishes of the public respecting the practical assertion of his social principles. This important change led to other changes in the society, including the introduction of marriage and family life; and in 1880 communism of property gave place to joint-stock, and the Community was legally incorporated as the Oneida Community, Limited. Each member now has a separate individual interest represented by shares of stock, in place of the undivided interest he formerly had in the common property. These changes were so wisely managed that the complex manufacturing and commercial businesses of the society were not seriously disturbed. In the division of the property of the Community, prior to its reorganization into a joint-stock company, a guarantee of support was first offered to all elderly and infirm persons in lieu of stock; secondly, a guarantee was pledged for the support and education of the children of the Community till sixteen years of age; thirdly, labour in the new company was guaranteed to all members of the old society; fourthly, some co-operative features were preserved, such as common dwellings and lawns, a common laundry, library, reading-room, &c.

Although the Oneida Community was started with very limited capital (the inventoried valuation of its property in 1857 being only $67,000), and hard work and poor fare were the lot of its members for many years, yet industry and business integrity brought their usual rewards, and upon the reorganization the members were able to divide $600,000. The last annual report of the Oneida Community, Limited, filed with the secretary of state at Albany, New York, shows that its assets, 1st January 1884, were $785,656,—a sum covering, not only its capital stock of $600,000, but a surplus fund of $24,050, and all liabilities against the company.

The Oneida Community, Limited, owns water-powers and factories at Wallingford, Connecticut, and Niagara Falls, New York, as well as at Community, New York; but its business is principally carried on at the two places last named. At Wallingford there existed, previous to the reorganization, a branch community, varying from thirty to sixty members, and having a common interest in the parent society,—both men and means being transferred from one society to the other as occasion required.

The Oneida Community has been often described by writers not connected with the society, the most noteworthy being Colonel T. W. Higginson, Professor Goldwin Smith, Charles Nordhoff in *Communistic Societies of the United States*, and William H. Dixon in *New America*. The Community also published many pamphlets and larger works in exposition of its principles and social life, and a newspaper during its entire career of thirty years. These may be consulted in several of the public libraries of the United States, and also in the British Museum, which has a complete set of the publications of the Oneida Community. The following list includes the more important books and pamphlets:—*History of American Socialisms*, by John H. Noyes, 1870; *Berean*, *Home-Talks*, *Salvation from Sin*, *Male Continence*, *Scientific Propagation*, *Dixon and his Copyists*, all by the same author; *Report on the Health of the Children of the Oneida Community*, by Dr T. R. Noyes; *Foot-Notes*, by Alfred Barron; *Mutual Criticism*, and *American Communities*, by William Alfred Hinds. (W. A. H.)

'ONEIZA, or 'ANEYSA, a town in the Nefúd or sand country of Al-Kasím and, after Riad, the most considerable place in Nejd or highland Arabia, appears to have been founded about 500 years ago,[1] near the now ruined village of Jennah (settled some centuries before by colonists of the Baní Khálid). These new places were in the circuit of the old Baní Tamím towns destroyed by the sword of Khálid b. Walíd, whose sites are now named Al-'Eyaria (Manzil 'Eyar) and Al-Owshazía. Colonists of the Ḳaisite stock of Sbeya Arabs were the first builders of 'Oneiza, and the emirs of the township are still of this blood. After them came in colonists of the Tamím, who now form the chief element in the population. The old faction warfare between the villages Jennah and 'Oneiza was incessant, and the Baní Khálid had the greatest name in Nejd till the rise of the Wahhábite power. Jennah then made alliance with the Montefiḳ Arabs in the north; 'Oneiza sided with the Wahhábites, and, these soon overrunning all, a part of the Jennah villagers abandoned their country, and went to live in Mesopotamia, and the rest came in to inhabit 'Oneiza. The site of their old village is now in the orchards of 'Oneiza, enclosed by the common town-wall.

'Oneiza is built upon an old *seil* (freshet) strand (2600 feet above sea-level), and has been sometimes damaged by floods; the houses are of clay; the population, greatly increased, as Mr Doughty was told, in the fifteen years preceding his visit, was computed by him at nearly 7000. The site is near the great Wádí al-Romma (comp. Yáḳút,

[1] The name belonged to the site before there was a town (see Bekri and Yáḳút), and the same place is probably meant by the dual 'Oneizatein in 'Antara's *Mo'allaḳa*.

iii. 738), and beyond the wádi, at 11 miles' distance, is the other great township of Middle Nejd, Boreida, less than 'Oneiza, with a population probably of 5000.

The people of these and the neighbouring towns, as Al-Rass,[1] are in great part caravaners and merchants; they are the Lombards of Arabia, and are called in the Mecca country "the easterlings," and in the Syrian and Mesopotamian border-lands the 'Azeil. These world-wandering men are commonly of easy, liberal mind in doctrines of religion, whilst the large half of their home-dwelling fellow-citizens are sour Wahhábites. In these upper parts of the peninsula we see yet some remains of the ancient Arabian civilization Here is found the art, elsewhere lost, of stone-cutting and well-building; and at 'Oneiza are goldsmiths whose work is among the best seen in the bazaars of Mecca. 'Oneiza has an appearance of commercial prosperity, but the poor farmers are much indebted to the money-lenders. The townsmen are among the greatest coffee-drinkers in Arabia. The horse-dealers of 'Oneiza procure young horses from the nomads round the town, even as far as Yemen, and ship these (known in India as "'Oneiza horses") at Koweyt for Bombay.

When Ibráhím Pasha marched to Nejd against the Wahhábite power this town was held by a resident for Ibn Sa'úd. Ibráhim shelled the clay fortress, but allowed the governor to depart with arms and baggage. After the building of Al-Riád 'Oneiza fell again to the Wahhábites. Jellowny, a brother of the Wahhábite prince Feysel ibn Sa'úd, was resident, but, bearing himself oppressively, he was expelled, as had been determined in a secret council of the sheikhs. This brought Ibn Sa'úd with all Nejd under arms, and the Shammar prince Ibn Rashíd, to recover the rebellious town. He encamped upon the borders of the Wádi al-Romma, and lay there till the second year (1853-54), but attempted nothing (since Arabs cannot be commanded or led to storm a clay town-wall even if, as in this case, it is no more than 18 inches thick), and then departed, making peace with the townsmen upon their own terms. A second war followed after eight years. Abdullah al-Azíz al-Mohammed, the natural prince of Boreida, worsted by the Wahhábite faction, fled to 'Oneiza; and a little later, when he was going to take refuge with the sherif of Mecca, the Wahhábites lay in wait for him in the desert and killed him. Word being carried to 'Oneiza, the townsmen sent out armed men, who overtook and fought with them because they had killed the guest of 'Oneiza, thus drawing a new conflict on the town. Mohammed, another brother of the prince Ibn Sa'úd, came against 'Oneiza, and all subject Arabia in arms with him; and to meet this multitude 'Oneiza had little more than 1000 men. The Wahhábites had cannon, but could not handle them; the 'Oneizians, in their walled township, followed their daily labours at leisure. The citizens made one sally in force, but after heavy fighting were driven back with a loss of 200 men. There were two slighter skirmishes in long months of warfare. At length the besiegers, impatient of the time vainly spent, drew homeward, and Ibn Sa'úd returned to Al-Riád.

ONKELOS. See TARGUM.

ONOMACRITUS was a seer, priest, and poet of Attica about 530-480 B.C. His importance lies in his connexion with the religious movements in Attica during the 6th century. He had great influence on the development of the Orphic religion and mysteries; and the works of Musæus, the legendary founder of Orphism in Attica, are said to have been reduced to order by him (see ORPHEUS). He was in high favour at the court of the Pisistratidæ till he was detected by Lasus of Hermione making an interpolation in an oracle of Musæus, and was banished by Hipparchus. When the Pisistratidæ were themselves expelled and were living in Persia, Onomacritus is said to have furnished them with oracles encouraging Xerxes to invade Greece and restore the tyrants in Athens. He is also said to have interpolated Homer, and has in modern times been considered by some critics to have remodelled the Homeric poems.

XXIII. ONTARIO is the name given under the confederation of the provinces of British North America to what was previously known as Upper Canada (see CANADA). The river Ottawa, through a considerable part of its course, forms the eastern boundary separating it from the province of Quebec. Its southern and south-western boundaries are the Lakes Ontario, Erie, St Clair, Huron, and Superior, with the St Lawrence, Niagara, St Clair, Detroit, and St Mary rivers. The northern and western boundaries, which had remained without precise determination so long as the region beyond was the hunting-ground of the Hudson's Bay Company, were defined in 1878 by arbitrators named by the Dominion and provincial Governments. By this award the boundary line is traced from a point determined by a line produced due north from the head of Lake Temiscaming to James Bay, along the south shore of Hudson's Bay westerly to the mouth of the Albany river, and so by the river and lakes to the head of Lake Joseph, and by Lac Seul and the English river to a point of intersection with the meridian line drawn from the north-western angle of the Lake of the Woods on the United States boundary. The legislature of Ontario accepted this award as determining the limits, and defining the boundary line between the provinces of Ontario and Manitoba, but the Dominion Government withheld its assent, and the final decision is now referred to the privy council. The area of the province within the limits thus defined would be 197,000 square miles. Its area as given in the census returns of 1881 is 101,733 square miles.

Geology and Minerals.—The shores of Lakes Erie and Ontario belong to the great plain of Canada, underlaid by Silurian and Devonian limestone and shales, above which rest beds of clay and gravel. Its average breadth is about 70 miles, and, though technically a plain, it is not merely undulating, but is broken by shelving rocks and precipices. To the north of the province a spur from the Laurentian chain in Quebec forms an extensive hilly region, and runs southwards to the coasts of Lake Huron and the Georgian Bay. Within the province there is a great variety of mineral wealth yet only partially developed. Iron, of which, according to the census returns, the annual yield is about 92,000 tons, is found in large quantities to the north of Lake Ontario, between the Georgian Bay and the Ottawa river. Magnetic iron is obtained in various beds, red hematite in the Bruce copper-mines near Lake Huron, and bog iron in the sandy tracks which flank the Laurentian hills. Copper is found in the same region as iron, the Bruce mines yielding ore to the annual value of £50,000. Silver abounds on the shores of Lake Superior, especially in the neighbourhood of Thunder Bay,—Silver Islet, where the ore is dug 500 feet below Lake Superior, containing one of the richest veins in the world. Gold is obtained in the same region, but the yield is so uncertain as to discourage regular enterprise. There are petroleum wells of immense value in the western districts of the province, the annual yield being nearly 16,000,000 gallons of crude petroleum. Salt brine is drawn up from deep wells at Goderich and the neighbourhood, the annual yield being about 500,000 gallons. Mica is extensively worked. Marble equal to that of Carrara is quarried in several districts. The principal other minerals are galena, plumbago, antimony, arsenic, manganese, calc-spar, and gypsum.

Agriculture and Trade.—The oldest settled districts of the province on the shores of Lakes Ontario and Erie, and on the intervening peninsula of Niagara, are favoured in many respects by geographical position, soil, and climate. The fertile area stretching westward between Lake Erie and the Georgian Bay is often styled the "Garden of Canada." The settled portions include upwards of 9,000,000 acres, much of which has been long cleared and brought into a high state of cultivation. Thousands of acres are planted as orchards; and the apple crop is a

[1] Near Al-Rass is Al-Ethella, the site, probably, of Járada, the [illegible] of Kasim.

profitable branch of farm produce. In the still earlier settled district of Niagara, which lies between the two great lakes, the extremes alike of summer heat and winter cold are tempered by those large bodies of water. There accordingly the peach, grape, and plum flourish; orchards of apple and pear trees cover large areas; and, as seen from Queenston heights, the landscape looks like a garden. The vine is indigenous, and grows luxuriantly in the woods, as do all the smaller fruits.

But the energy of more recent settlers has greatly extended cultivation. Bands of pioneers, lumber-men, and free-grant settlers have carried the axe and the plough into the Muskoka, Nipissing, and other northern districts; and those regions are now accessible by steamboat and railway. The rich mineral regions of Lake Superior are also filling up with settlers. The town of Prince Arthur's Landing, at the head of the lake, is now the terminus of the Canadian Pacific Railway, and already numbers fully 2000 inhabitants.

According to the census of 1881, 19,259,909 acres were in occupation, of which 11,294,109 were improved, 304,815 being in gardens and orchards, and 10,989,294 under cultivation in pasture or grain and root crops. Much of the land is well adapted for wheat, but in many places the crop has been grown too often. Barley, oats, and pease are common crops. Maize and tomatoes ripen well. Tobacco and sugar are profitable crops in some districts. The growth of flax is largely on the increase. As the soil in nearly every part of the province is admirably adapted for root crops, cattle are very largely kept, although there are no extensive grazing districts. The beef trade with England has become very extensive, and dairy-farming is largely prosecuted, especially the making of cheese, a large number of cheese factories being now established on the co-operative principle. Honey is an important source of revenue, about 1,200,000 ℔ being exported annually. There is a very large export of timber, including pines, oak, elm, hackmatack, birch, maple, walnut, and hickory. In the official returns of the exports of the different provinces some of the most valuable produce of Ontario is included in the shipments from the ports of Quebec. According to the trade and navigation tables for 1883, the total value of goods entered for consumption was \$44,452,804, or £9,134,143, and of exports \$32,890,019, or £6,758,242. The splendid natural water communications have been extensively supplemented by railways, of which there are about 4000 miles in operation. There are very extensive saw-mills at Ottawa. The manufacture of agricultural implements employs a large number of persons throughout the province, as does also that of machinery, sewing-machines, and edged tools. Among the principal other manufactures are woollen goods (especially tweeds), cottons, leather, paper, soap, and iron and hardware. According to the census returns the total capital invested in the various industries, not including agriculture but including cheese factories, was \$80,950,847, the number of hands employed 118,308, and the total value of products \$157,989,870.

Population.—The population in 1871 amounted to 1,620,851; in 1881 it had increased to 1,923,228. Of this, the population of twelve towns of upwards of 5000 inhabitants numbered in 1871 179,829. In 1881 the towns of a population exceeding 5000 had increased from twelve to nineteen, with inhabitants numbering 288,964, leaving the remaining population as occupants of the small towns, rural villages, and farms. At the end of 1883 the population was estimated at 1,935,130 (urban, 671,917; rural, 1,263,213).

Classified according to race, those of European origin were as follows in 1881:—

Irish	627,262	Swiss	2,362
English	535,835	Scandinavian	1,521
Scotch	378,536	Russians and Poles	787
German	188,394	Italians	687
French	102,743	Spanish and Portuguese	285
Dutch	22,163	Jews	254
Welsh	6,397		

In addition to those from other provinces, the United States, &c., there were 15,325 Indians and 12,097 Africans.

Classified according to religion, the principal denominations were in 1881 as follows:—

Methodists	591,503	Lutherans	37,901
Presbyterians	417,479	Congregationalists	16,340
Episcopalians	366,539	Disciples	16,051
Roman Catholics	320,839	Quakers	6,307
Baptists	106,680		

The capital of the province is Toronto (population in 1881, 86,415); next in point of wealth, population, and general local advantages is the city of Hamilton (35,961); Ottawa (27,412) is the capital of the Dominion; the other large centres of population are London (19,746), Kingston (14,091). Next to these are Guelph, St Catherine's (on the Welland Canal), Brantford, Belleville, St Thomas, Stratford, Chatham, Brockville, Peterborough, Port Hope, Woodstock, Galt, and Lindsay, with populations ranging from 9890 to 5080. Cobourg (4957) is the seat of Victoria College.

Education.—One of the most distinctive features of the province is its system of public instruction, to which special attention has been given from an early period. So early as 1797 lands were set apart for educational purposes; and there now exists a thoroughly efficient system of public schools, high schools and collegiate institutes, provincial college and university, under the administration of a minister of education as the head of this department. The management of all funds for general educational purposes, the provincial school inspectors, normal and model schools, &c., are under the direct charge of the educational department. Under its control the local government is vested in boards of school trustees elected by the ratepayers in rural districts or townships, villages, towns, counties, and cities, in accordance with a general system of municipal organization. Each local board determines the required rates to be levied for school purposes, purchases sites, builds schoolhouses, appoints teachers from among those duly qualified and holding Government certificates, and determines and pays their salaries. The councils of county municipalities have certain powers and duties conferred on them in reference to the townships, villages, and towns within each county. They also select duly qualified inspectors, appoint county boards for the examination of third-class teachers, and levy a rate equivalent to the amount of the legislative educational grant to be expended in the payment of one-half of the salaries of their teachers and school inspectors. Collegiate institutes and high schools (in which a higher English course is taught, along with classics, mathematics, and French and German, to pupils admitted from the public schools on an entrance examination) are under the management of special boards of trustees appointed by city or county councils, with the power of requiring the council to raise all funds requisite for the efficient maintenance of the schools. Provincial normal schools for training teachers are established at Toronto and Ottawa, with model schools attached to them; and each county town maintains a model school for training third-class teachers. The school-system is thus mainly dependent on county and local rates levied for the purpose by councils and school-boards elected by the people. This general system is modified in one respect. In any locality where Roman Catholics reside in sufficient numbers, they may require their share of the school funds

and rates to be applied for the maintenance of separate schools, under their own special school-board; but their teachers must hold the same Government certificates as others. The system includes provision for enforcing attendance of all children of school age, and, at the option of the trustees, making education free of all charge. The report of the minister of education for 1882 shows that there were in all 104 collegiate institutes and high schools, 5013 public schools, and 193 Roman Catholic separate schools. The system thus thoroughly organized has become a model for the other provinces of the Dominion, with the exception of Quebec, where the Roman Catholic Church has the control of the public schools, and a separate school-system is allowed for the Protestant minority.

Upper Canada College, founded at Toronto on the model of the great public schools of England, was endowed with public lands, from which it now derives an annual income of $15,000 in addition to its fees. The University of Toronto and University College are endowed with lands from the proceeds of which an annual income of upwards of $67,000 is derived. The university prescribes the requirements in all examinations, appoints examiners, and confers degrees in the faculties of law, medicine, and arts. University College gives instruction in the departments of arts and science; but denominational and other colleges are admitted to affiliation, and their students can proceed to degrees in the university. University powers are also exercised by Victoria College, Cobourg, under the control of the Methodist Church; Queen's College, Kingston, under the control of the Presbyterian Church; and Trinity College, Toronto, and the Western University, London, both under the control of the Church of England.

Administration.—Like the other provinces of Canada, Ontario is under a lieutenant-governor, appointed for a term of four years by the governor-general in council; the executive council numbers 6 ministers responsible to the local legislature or house of assembly, which consists of 88 members. The province is represented by 24 senators in the Dominion Senate, and by 92 members in the House of Commons. In addition to the counties and representative towns there are four provisional districts:—Algoma, Muskoka, Parry Sound, and Manitoulin.

History.—Lakes Ontario and Nipissing were visited by Champlain in 1615, and Lake Superior by traders in 1660. Perrot took possession of the district round Lake Huron in 1671. La Salle founded Niagara in 1679, and in the same year the lakes were explored to Lake Michigan. A fort was built at Toronto in 1749. Forming originally part of French Canada, Ontario, then consisting of a few forts and trading ports, was conceded with that province to Britain. Having previously formed part of the province of Quebec, it was, under the name of Upper Canada, formed in 1791 into a distinct province, the first parliament being held at Niagara, 17th November 1792. During the war with the United States in 1812-15 the province was the seat of several conflicts. Political dissent prevailed in it from 1820 until, in 1837, it culminated in rebellion. In 1867 Upper Canada, under the name of Ontario, was made the chief province of the Dominion of Canada. (D. W.)

ONTENIENTE, an old town of Spain, in the province of Valencia, stands on an elevation on the right bank of the Clariano or Onteniente, a sub-tributary of the Jucar, about 11 miles south-south-west from Játiva. It has three churches, a good town-hall, and a palace of the dukes of Almodovar. Linen and woollen cloth, paper, brandy, and earthenware are manufactured; and there is also some trade in the cereals, wine, and oil produced in the neighbouring district, which is very fertile. In 1877 the ayuntamiento had a population of 11,727.

ONTOLOGY. See METAPHYSIC.

ONYX, a variety of agate consisting of layers of variegated chalcedony, arranged in parallel bands. The colours of the successive strata vary in different stones, but in the typical onyx they are black and white. If one of the layers consists of the brown chalcedony known as "sard" or the red variety called "carnelian," the resulting stone is termed a "sardonyx." It was probably this kind of stone that originally suggested the name "onyx" (from ὄνυξ, a nail), since the contrast between its layers remotely resembles that between the flesh-coloured part of the finger-nail and the white *lunula* at its root. It was the practice of certain Greek writers to restrict the word ὄνυξ to the mineral in its natural condition, and to designate it, when worked into ornamental forms, by the diminutive ὀνύχιον. When an onyx presents a thin layer of whitish chalcedony spread over a black ground, the upper stratum often exhibits a bluish tinge, and collectors at the present day term such a stone a *nicolo*, evidently a corruption of the Italian diminutive *onicolo*, or "little onyx."

India has for ages yielded the finest onyxes, and hence jewellers are in the habit of applying the expression "Oriental onyx" to any stone distinguished by beauty of natural colour and by regularity of its layers. The true Indian stones are found as pebbles, associated with moss-agate, jasper, and other silicious minerals in river-gravels, the materials of which have been derived originally from the agate-nodules of trap-rocks, such as those which occur on an enormous scale in the Deccan. As far back as the first century the author of the *Periplus* of the Red Sea mentions the onyx among the products of Plythanæ, a locality which may probably be identified with Paithon on the Godavari, whence agates are obtained even at the present day. He further states that the onyxes were taken down to Barygaza, the modern Broach, where a great trade in agates is still carried on. It appears that the lapidaries of Broach and of Cambay are now supplied with raw stones chiefly from Ratanpur, in the territory of the rajah of Rajpipla, where the gravels are systematically worked for the sake of their agates, jasper, onyx, and other silicious stones. See Ball's *Economic Geology of India*, 1881, p. 503.

The principal European locality for onyx is the neighbourhood of Oberstein on the Nahe, a river which flows into the Rhiné at Bingen. Near Idar, about two miles from Oberstein, is a trap-hill called the Galgenberg, which for centuries was largely worked by means of tunnels driven into the hillside, in order to extract the nodules of agate which are embedded in the melaphyre forming the rock. When these nodules are broken open they occasionally yield a banded chalcedony which serves admirably for onyxes. The quarries have, however, been abandoned for many years in consequence of the discovery of larger and finer nodules in Uruguay, principally among the gravels of the Tarquarie and the Rio Pardo. These agates are still sent over in large quantities to Oberstein, where the cutting and polishing of such silicious stones form almost the sole industry of the locality. Coming from South America, they are commonly known in trade as "Brazilian agates"; and it is from these agates that most of our onyx is now obtained.

It is but rarely that the South-American agates present in their natural condition sufficient diversity of colour to constitute a good onyx, but for many years it has been the practice of the German agate-workers to colour these stones artificially. By this means an agate of dull colour may be rapidly converted into a deep-tinted onyx, the successive layers becoming sharply defined and vividly coloured during the process of staining. How this dyeing is effected has been described in the article AGATE, vol. i. p. 277.

The onyx is largely employed for ring-stones, brooches, beads, and other ornamental objects; but its chief use is as a material for *camei* and *intagli*. By taking advantage of the different tints of the strata in this stone, a skilful artist is enabled to produce effects of a very pleasing character. Among the finest examples of ancient stone-

engraving which have descended to us are certain vessels in onyx, elaborately ornamented with cameo-work, such as the Cup of the Ptolemies, the Farnese Tazza, and the Mantuan or Brunswick Vase.

According to the Authorized Version of the Old Testament, the onyx formed the eleventh stone in the breast-plate of the high priest; but it is more probable that this stone (שֹׁהַם) is the beryl, and that the onyx is יָהֲלֹם, Exod. xxxix. 11 (E. V. diamond).

It is pointed out by the Rev. C. W. King that the earliest mention of the onyx as a precious stone is to be found in the inscriptions of the Parthenon, which date from the Peloponnesian War (431-404 B.C.), where a large engraved onyx is mentioned as an offering. It is to be specially noted that ancient writers applied the term ὄνυξ to two entirely different stones. While one of them was the true onyx of modern mineralogists, as described above, the other was merely a stalagmitic variety of carbonate of lime, a mineral much softer, less precious, and much more widely distributed than the chalcedonic onyx, yet resembling it in so far as it also presents a parallel-banded structure. This mineral is still known as "onyx-marble" (see MARBLE, vol. xv. p. 529).

OODEYPORE, or UDAIPUR. See vol. v. p. 768.

OPAH (*Lampris luna*), a pelagic fish of the family *Coryphænidæ* or Dolphins. It differs from the typical dolphins (*Coryphæna*) materially in the shape of its body and the structure of the ventral fins. Instead of being elongate, the body is compressed and deep (more so than in the bream), and destitute of distinct scales. A long dorsal fin, high, and pointed anteriorly, runs along nearly the whole length of the back; the caudal is strong and deeply cleft. The ventral fins are broad paddles pointed at the extremity, and composed of numerous rays. This latter character is quite exceptional in the order of spiny-rayed fishes, but finds its explanation in the habits of the fish. A pelagic fish with so deep a body and so short a tail as those of the opah requires additional propelling power to be able to find or pursue its prey; and therefore to the ordinary function of the ventral fins, which in other fishes is confined to balancing the body in the water, has been superadded that of locomotion.

In its gorgeous colours the opah surpasses even the dolphins, all the fins being of a bright scarlet. It is only occasionally found near the shore: its real home is the Atlantic, especially near Madeira and the Azores, but many captures are recorded from Great Britain, Ireland, and Scandinavia; it strays as far north as Iceland and Newfoundland, and probably southwards to the latitudes of the coast of Guinea. It is rare in the Mediterranean. The name opah, which is now generally used, is derived from the statement of a native of the coast of Guinea who happened to be in England when the first specimen was exhibited (1750), and who thought he recognized in it a fish well known by that name in his native country. From its habit of coming to the surface in calm weather, showing its high dorsal fin above the water, it has also received the name of "sun-fish," which it shares with *Orthagoriscus* and the basking shark. It grows to a length of 4 to 5 feet and a weight exceeding 100 lb, and is highly esteemed on account of the excellent flavour of its flesh.

OPAL, a natural form of hydrated silica, occurring in a "porodine" condition, *i.e.*, it has apparently hardened from a gelatinous state. During consolidation it has suffered contraction unequally in different directions; and thus, though amorphous, it behaves in polarized light like a doubly-refracting body.

The beautiful variety known as *noble* or *precious opal* is remarkable for its play of iridescent colours. In the "harlequin opal" these rainbow-tints are flashed forth from small flakes, forming a kind of polychromatic mosaic, while in other kinds of opal the colours are disposed in broad bands or in irregular patches of comparatively large area. The tints vary with the angle at which the light is incident, and with the relative position of the stone and the observer, so that by moving the opal a brilliant succession of flashes of fire may be obtained. Careful examination of a precious opal shows that these flashes are reflected from surfaces of irregular dimensions, situated at different depths in the translucent stone, and intersecting at various angles. The colours are not due to the presence of any material pigment in the mineral, but are optical effects due to certain structural peculiarities.

According to Sir David Brewster the colours of the opal may be referred to the presence of multitudes of microscopic pores arranged in parallel lines, the differences of tint arising from differences in the magnitude of these cavities. M. Descloizeaux, a very high authority on the optical properties of minerals, has also connected the iridescence of the opal with a regular system of internal cavities, but at the same time seems disposed to think that the colours bear some relation to the presence of a small quantity of organic matter in the mineral. Mr Crookes refers the colours to delicate striæ or minute fissures lying in different planes within the opal. The whole subject has been exhaustively studied by H. Behrens, who explains the colour as due not to reflexion from the walls of cavities but to the interposition of very thin lamellæ possessing a different index of refraction from that of the matrix in which they are embedded. He has detected in the opal a variety of microscopic enclosures, including flecks of hydrophane and delicate laminæ of ferric oxide. On the whole, therefore, it seems likely that the iridescence of the opal is simply a case of the well-known colours of thin plates. A ray of light is reflected from the anterior surface of an attenuated film; another ray, having traversed the lamina, is reflected from the posterior surface; and the meeting of these rays differing in phase gives rise to interference phenomena.

The noble opal, in consequence of its brilliant iridescence, is valued as an ornamental stone. It is displayed to best advantage when cut *en cabochon* or with a convex surface. Pliny relates that the rich Roman senator Nonius was proscribed by Mark Antony for the sake of a magnificent *opalus* which he possessed, a stone as large as a hazel nut, and valued at 20,000 sesterces.

The precious opal occurs in veins in trachytic rocks, chiefly in Hungary. The best-known localities are Czerwenitza and Kaschau, but the most brilliantly-coloured stones are said to come from Kremnitz and Dubnik. It is found also in Honduras, principally near Gracias a Dios, where it occurs in like manner, forming veins in volcanic rocks. The American opal is generally less milky and less fiery than the Hungarian. Of late years some very brilliant opal has been sent into the market from Queensland. This is found as thin films spread over the walls of fissures in ironstone nodules, occurring in the neighbourhood of the Baracorra river. It is generally too thin to be cut *en cabochon*, but is largely used for cameos, the iridescent layers showing to great advantage against the ironstone matrix, which when polished assumes a dark-brown colour. The so-called "black opals," which have lately become popular, consist of this matrix penetrated in all directions by veins and spots of opal, forming a mixture sometimes known as "root of opal." Certain stones sold as black opals have evidently been modified in colour by staining or by heat.

See Brewster, "On the Cause of the Colours in Precious Opal," *Edin. New Phil. Journ.*, xxxviii., 1845, p. 385; Descloizeaux, *Manuel de Minéralogie*, vol. i., 1862, p. 22; Crookes, "On the Spectral Phenomena of Opals," *Quart. Journ. Science*, vi., 1869, p. 481; and especially Behrens, "Mikroskopische Untersuchungen über die Opale," *Sitzungsber. d. k. k. Akad. d. Wissenschaften, Wien; math.-naturwiss. Classe*, lxvi., 1871, p. 519. For a mineralogical description of the varieties of opal see MINERALOGY, vol. xvi. p. 390.

OPENSHAW, a township of Lancashire, England, is situated on the Manchester and Stockport Canal, about $3\frac{1}{2}$ miles east from the Manchester exchange. The church of St Barnabas dates from 1838-39, and that of St Clement from 1871. The mechanics' institute (1872) comprises assembly rooms with a reading-room and library. The town possesses railway-carriage and locomotive works, engineering shops, iron-foundries, cotton-mills, dyeworks, chemical-works, and breweries. The area of the township is 579 acres; population in 1871, 11,108; in 1881, 16,153.

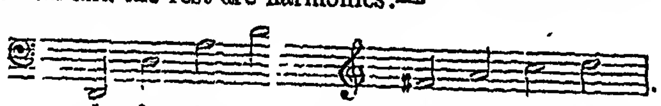
OPERA. See DRAMA, vol. vii. p. 437, and MUSIC.

OPHICLEIDE is a brass musical instrument with keys. It belongs to that class of instruments in which the column of air is set in vibration by a trembling of the lips applied to the edge of a hemispherical cup at the extremity of the tube, called the "embouchure." The lips vibrate from the action of the breath and play the part of reeds; the degree of pressure of the embouchure determines the rapidity of their vibration, on which, concurrently with the length of the tube, depends the pitch, or relative position, of the sound produced.

The name "ophicleide" is compounded of two Greek words, ὄφις, serpent, and κλεῖδες, keys,—the instrument owing, in fact, its origin to the application of keys to the serpent, a wind instrument the invention of which is generally attributed to Edme Guillaume, canon of Auxerre, somewhere about 1590. He contrived it to serve as a bass to the zinken, instruments now entirely obsolete.

FIG. 1.—The Serpent.

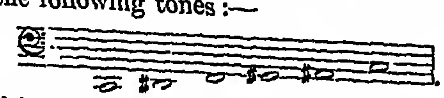
The serpent, represented by fig. 1, is composed of two pieces of wood, hollowed out and cut to the desired contour. They are joined together by gluing so as to form a tube, and are bound with leather to ensure solidity. The upper extremity ends with a bent brass tube or crook, to which the mouthpiece is applied. The tube is pierced laterally with six holes, the first three of which are covered by three fingers of the right hand, and the others by the corresponding fingers of the left hand. When all the holes are thus closed the instrument will produce the following sounds, of which the first is fundamental and the rest are harmonics:—



1 2 3 4 5 6 7 8

The instrumentalist fills up the gaps in the diatonic or natural scale by the successive opening of the lateral holes after the manner practised in fingering the flute. The serpent remained in its primitive form for nearly two centuries, and then only it was attempted to improve it by adding keys. From the time of its origin it had served principally as an accompaniment to the liturgical chanting, but towards the middle of the 18th century it began to be employed as a bass for military music, and, notwithstanding its numerous imperfections, it was but slowly given up.

Fig. 2 represents a curious serpent made, about 1830, by L. Embach and Co., Amsterdam. The six lateral holes are here placed more rationally along the tube, but, being beyond the reach of the fingers, they are covered by open keys, besides which the instrument also bears six closed keys for the following tones:—



The primitive form of the serpent was most inconvenient, and it was a musician named Régibo, belonging to the orchestra of the church of St Pierre at Lille, who, about 1780, first thought of giving it the shape of a bassoon (Gerber, *Lexicon der Tonkünstler*, Leipsic, 1790). The merit of this innovation was rapidly recognized in England and Germany. Still to follow Gerber (*Lexicon*, 1812), one Frichot, who was established in London, published in 1800 a description of an instrument, entirely of brass, manufactured by J. Astor, which he claimed as his invention, calling it the basshorn, but which was no other in principle than the new serpent of Régibo. It only made its way to France and Belgium after the passage of the allied armies in 1815. We here reproduce (fig. 3) the drawing of a wooden serpent with bell and mouthpiece of brass, after a scale published by B. Schott of Mainz, in 1816. The English brass basshorn was designated on the Continent the English or the Russian basshorn, the "serpent anglais," or the "basson russe." Under this last name all instruments of the form, whether of wood or brass, were later on confounded in France and Belgium. The "basson russe" remained in great vogue until the appearance of the ophicleide, to disappear with it in the complete revolution brought about by the invention of pistons.

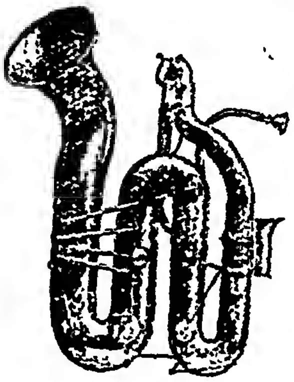


FIG. 2.—Serpent by Embach.

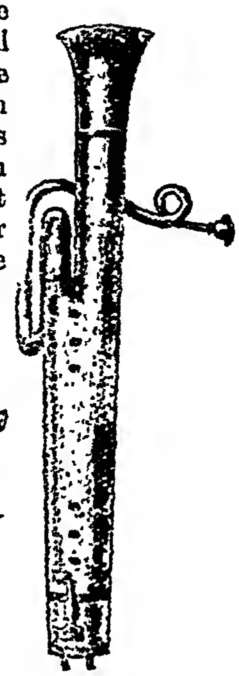

FIG. 3.—Wooden Serpent.

The invention of the ophicleide is generally but falsely attributed to Alexandre Frichot, a professor of music at Lisieux, department of Calvados, France. The instrument, which the inventor called "basse-trompette," was approved of as early as 13th November 1806 by a commission composed of professors of the Paris Conservatoire, but the patent bears the date 31st December 1810. The "basse-trompette," which Frichot in his specification had at first, in imitation of the English basshorn, called "basse cor," was, like the English instrument, entirely of brass, and had, like it, six holes; it only differed in a more favourable disposition brought about by the curvings of the tube, and by the application of four crooks which permitted the instrument to be tuned "in C low pitch and C high pitch for military bands, in C♯ for churches, and in D for concert use." The close relationship between the two instruments suggests the question whether this was the Frichot who worked with Astor in London in 1800.

The first idea of adding keys to instruments with cupped mouthpieces, unprovided with lateral holes, with the aim of filling up some of the gaps between the notes of the harmonic scale, goes back, according to Gerber (*Lexicon* of 1790), to Kölbel, a hornplayer in the Russian imperial band about 1754. Weidinger, trumpeter in the Austrian imperial band, improved upon this first attempt, and applied it in 1800 to the trumpet. But the honour belongs to Joseph Halliday, bandmaster of the Cavan militia, of being the first to conceive, in 1810, the disposition of a certain number of keys along the tube, setting out from its lower extremity, with the idea of producing by their successive or simultaneous opening a chromatic scale throughout the extent of the instrument. The bugle-horn was the object of his reform; the only scale of which, he says, in the preamble of his patent, "until my invention contained but five tones, viz., 

My improvements on that instrument are five keys, to be used by the performer according to the annexed scale, which, with its five original notes, render it capable of producing twenty-five separate tones in regular progression." Fig. 4 represents the keyed bugle of Joseph Halliday.

It was not until 1815 that the use of the new instrument spread upon the Continent. We find in the account-books of a Belgian maker, Tuerlinckx of Mechlin, that his first supply of a bugle-horn bears the date of 25th March 1815, and it was made "aen den Heer Muldener, lieutenant in het régiment duc d'York."

Fig 4.—Keyed Bugle.

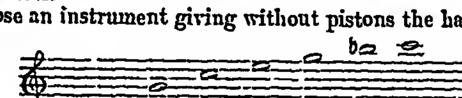
The acoustic principle inaugurated by Halliday consisted in binding together by chromatic degrees the second and third harmonics,  to . He attained it, as we have just seen, by the help of five keys. The principle once discovered, it became easy to extend it to instruments of the largest size, of which the compass, like the "basson russe," began at the lowest sound. It was simply necessary to bind the fundamental  to the next harmonic sound  by a larger number of keys. This was done in 1817 by Jean Hilaire Asté, known as Halary, a professor of music and instrument-maker at Paris. We find the description of the instruments for which he sought a patent in the *Rapport de l'Académie Royale des Beaux-Arts de l'Institut de France*, meeting of 19th July 1817. These instruments were three in number:—(1) the clavi-tube, a keyed trumpet; (2) the quinti-tube, or quinti-clave; (3) the ophicleide, a keyed serpent. The clavi-tube was no other than the bugle-horn slightly modified in some details of construction, and reproduced in the different tonalities A♭, F, E♭, D, C, B♭, A, and A♭. The quinti-tube had nearly the form of a bassoon, and was, in the first instance, armed with eight keys, and constructed in two tonalities, F and E♭. This was the instrument afterwards named "alto ophicleide." The ophicleide, of which we reproduce a drawing (fig. 5), had the same form as the quinti-tube. It was at first adjusted with nine or ten keys, and the number was carried on to twelve,—each key to give a semitone (additional patent of 16th August 1822). The ophicleide or bass of the harmony was made in C and in B♭, the contra-bass in F and in E♭.[1]

Fig. 5.—Ophicleide of Halary.

It is certain that from the point of view of invention Halary's labours had only secondary importance; but, if the principle of keyed chromatic instruments with cupped mouthpiece[2] goes back to Halliday, it was Halary's merit to know how to take advantage of the principle in extending it to instruments of diverse tonalities, in grouping them in one single family, that of the bugles, in so complete a manner that the improvements of modern manufacture have not widened its limits either in the grave or the acute direction. Keyed chromatic wind instruments made their way rapidly; to their introduction into military full or brass bands we can date the regeneration of military music. After pistons had been invented some forty years, instruments with keys could still reckon their partisans. Now these have utterly disappeared and pistons or rotary cylinders remain absolute masters of the situation.

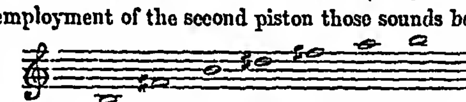
The invention of the piston is due to Stoelzel, a Silesian, and Blumel of Waldenburg (patent of 12th April 1818). It was first signalized by G. B. Bierey, leader of the National Theatre of Breslau, in No. 18 of the *Allgemeine musikalische Zeitung* (Leipsic, 1815). The inventors first applied their discovery to the horn, trumpet, and trombone, and this application consisted of only two pistons, or "ventile," as they called them. We have seen up to this point that chromatic intervals were produced in instruments with cupped mouthpiece by shortenings of the tube by means of lateral openings. It is evident that a column of air so cut off must be very inferior in sonorousness to one vibrating from the mouthpiece to the extremity of the bell; this has been the capital defect of keyed instruments. Stoelzel and Blumel proceeded in contrary fashion: they produced chromatic intervals by lengthening the tube, just as in the trombone with slides They introduced contrivances the movement of which permitted an instantaneous communication between the principal tube and two additional tubes, lowering the instrument respectively a tone and a half-tone, or by their simultaneous employment one tone and a half. As these combinations did not suffice to produce a complete chromatic scale, a third piston with an additional tube of a tone and a half was soon afterwards added by the inventors.

Suppose an instrument giving without pistons the harmonics

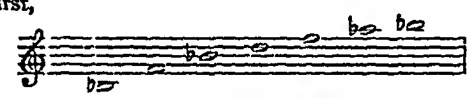


2 3 4 5 6 7 8

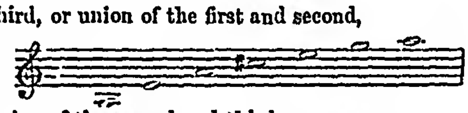
by the employment of the second piston those sounds become



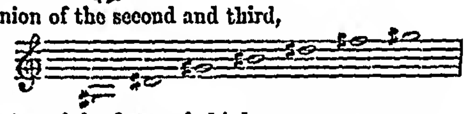
by the first,



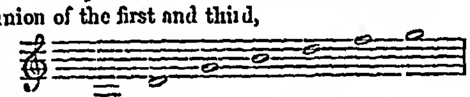
by the third, or union of the first and second,



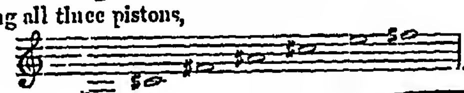
by the union of the second and third,



by the union of the first and third,



by joining all three pistons,



Here is the whole theory of the fingering of these instruments *à pistons*, of which the compass downwards is only bounded by the first harmonic.

A serious defect exists, however, in these piston instruments,—the want of truth of intonation whenever a note is produced by more than one piston. Let us take, for example, the low G . This note is produced, as we have just seen, by the union of the first and third pistons; in employing the first piston the pitch of the instrument is lowered a major second, and to produce the lowering to a fourth (two tones and a half) a further lowering of a minor third (one tone and a half) is necessary. Now the additional pipe to produce this lowering from C is necessarily proportionately shorter than what is required for a pipe already lowered a tone by the employment of the first piston. It therefore results, as will be seen from this special case, that all notes produced by several pistons at one time are too high in pitch.

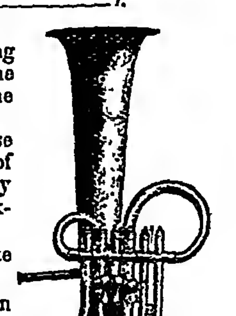


Fig. 6.—Ophicleide with pistons.

The invention of Stoelzel and Blumel, like all new ideas, was not accepted without opposition; notwithstanding its crushing superiority it had a lively struggle to sustain, and it is only within the last thirty years that the system of keys has been

[1] The report of the Académie des Beaux-Arts on the subject of this invention shows a strange misconception of it, which it is interesting to recall. "As to the two instruments which M. Halary designs under the names of 'quinti-clave' and 'ophicleide,' they bear a great resemblance to those submitted to the Academy in the sitting of the 11th of March 1811 by M. Dumas, which he designed under the names of 'basse et contrebasse guerrières.' . . . The opinion of our commission on the quinti-clave and ophicleide is that M. Halary can only claim the merit of an improvement and not that of an entire invention; still, for an equitable judgment on this point, we should compare the one with the other, and this our commission cannot do, not having the instruments of M. Dumas at our disposal." This is what the commission ought to have had, but it would have sufficed had they referred to the report of the sittings of 6th and 8th April, in which it is clearly explained that the instruments presented by M. Dumas were bass clarinets (*Moniteur Universel* of 19th April 1811)

[2] We designedly omit the employment of the word "brass" to qualify these instruments. The substance which determines the form of a column of air is demonstrably indifferent for the *timbre* or quality of tone so long as the sides of the tubes are equally elastic and rigid.

finally superseded by pistons. We close this article with the curious representation (fig. 6) of an ophicleide *with pistons* manufactured about 1836 by C. Mahillon of Brussels, then at the beginning of his career. (V. M.)

OPHIR (אוֹפִיר), a place famous among the Hebrews for its gold from the time of Solomon, whose Red Sea fleet, in conjunction with the Phœnicians, went to Ophir and brought thence a vast treasure of gold with precious stones and "almug" wood (1 Kings ix. 28, x. 11). It is quite plain from Gen. x. 29 that Ophir belonged to southern Arabia, from which the Phœnicians still derived gold and precious stones in the time of Ezekiel (xxvii. 22). All attempts to place Ophir in India or on the east coast of Africa (Sofála) are at variance with Gen. x. It is true that Indian products were also brought to Solomon (1 Kings x. 22), but these are not said to have come from Ophir, and therefore we cannot even be sure that Ophir was the emporium where the Indian trade and the Western met, as they did in southern Arabia in later times,—unless, indeed, the "almug" or "algum" wood is, as has been conjectured, the Indian sandalwood.

OPHITES. See Gnostics.

OPHTHALMOLOGY. The scientific development of the diagnosis and treatment of diseases of the eye belongs to the last hundred years. Helmholtz's invention of the ophthalmoscope is little more than thirty years old. Our knowledge of the refraction and accommodation of the eye has been worked out by Airy, Young, Sanson, Purkinje, Donders, Sneller, Helmholtz. Many of the major operations have been perfected by Von Graefe and his followers in quite recent times. Finally, the important relations of ophthalmology to general medicine have been worked out principally by Hutchinson, Hughlings Jackson, Clifford Allbut, and Gowers within the last few years.

Diseases of the conjunctiva.

Acute Catarrhal Conjunctivitis begins with a feeling of stiffness of the lids, and pain as if from a particle of grit in the eye. The secretion increases, is at first watery, and is afterwards yellow and muco-purulent, collecting at the inner canthus and gumming the eyelids together. The conjunctiva, especially that on the lids, is reddened, and in severe cases may be so swollen as to overlap the cornea. The eye is generally well in a fortnight. The disease is caused by cold winds, and by irritating particles, and in one form is undoubtedly contagious. The eye must be left uncovered, bathed occasionally with an astringent lotion, and at night some ointment should be applied to the edges of the lids to prevent their adhesion and consequent retention of the secretion.

Chronic conjunctivitis may result from the above, or be due to the irritation of dust. It occurs frequently from overstrain of hypermetropic eyes. The symptoms are similar, but less severe, and require similar treatment with correction of the hypermetropia where present.

Purulent Ophthalmia[1] (ophthalmia of the newly born) is caused by contact of pus from a gonorrheal or leucorrheal discharge or from another eye similarly affected. It is one of the forms of Egyptian ophthalmia. In children both eyes are generally affected; in adults usually one. The symptoms begin, from one to three days after infection, with a watery discharge, which increases rapidly in amount, and becomes yellow and purulent. The conjunctiva becomes greatly congested and swollen, bleeding readily. The lids are so stiffened with infiltration that they can hardly be separated. When they are slightly opened quantities of pus escape. There is great pain in the eye, fever, and sleeplessness. The cornea is much endangered; it may be perforated, may slough wholly or in part, and the eyeball may be destroyed. If one eye only is affected the other must be protected. Locally the greatest cleanliness is necessary, and the discharge must be constantly removed. Once daily the conjunctiva should be touched with a strong solution of nitrate of silver, and in the interval frequently bathed with astringent solutions. Recently, powdered iodoform has been much recommended as a local application. In adults leeching the temple and the continuous application of ice to the eye may be needed. The attendants must be warned of the danger of conveying infection to their own eyes.

Diphtheritic Conjunctivitis is characterized by the formation of a yellowish false membrane on the conjunctiva, which becomes thickened and almost solid from infiltration, and by great liability to sloughing of the cornea. It occurs most frequently in North Germany, attacking weakly children during epidemics of ordinary diphtheria, and, like it, often proves fatal by exhaustion. It should be treated by the internal administration of tonics and stimulants, and by the local use of ice, antiseptic lotions, and the strictest attention to cleanliness.

Chronic Granular Conjunctivitis is a contagious disease arising from prolonged overcrowding under bad sanitary conditions. It is thus specially common among the Jewish and Irish poor, and among workhouse children. The mucous membrane of the lids becomes reddened, thickened, and studded over with small firm "granulations," like boiled sago grains. The friction of these bodies produces a vascular opacity of the cornea (pannus), at first limited to the upper half of the cornea, but in bad cases involving its whole surface. There is considerable pain and discharge, and the eyelids are kept half-shut. There is a peculiar liability to acute exacerbations. The conjunctiva finally shrinks to a dense white scar, which curves the tarsal cartilage inwards, and brings the edge of the lids and the eyelashes to rub on the cornea, and increase its opacity.

It must be persistently treated by strong astringent or caustic applications to the conjunctiva. The pannus, as a rule, disappears with the granulations that caused it. If not, a zone of conjunctiva round the cornea may be divided; or, as a last resort, the eye may be inoculated with pus from a purulent case. All acute exacerbations must be treated by soothing applications. Incurving of the tarsal cartilage and displacement of the lashes need special surgical operations, which are more or less successful.

If a case occurs in a school or in barracks it must be at once isolated.

Pterygium is a triangular thickening of the exposed part of the conjunctiva, which may or may not be vascular. Its apex is towards the cornea, over which it tends to grow, and thus to interfere with vision; otherwise it causes no irritation. Pterygium is a disease of middle life and of warm climates. If it cause no deformity or interference with sight it should be left alone. If large it may be dissected up from the apex and cut off, or transplanted into another part of the conjunctiva, where it will shrivel up.

Dis of t cor

The diseases of the cornea are of extreme importance, from their great frequency and from the fact that a small lesion may seriously affect the perfect transparency and regularity of curvature so necessary for clear vision.

Chronic Interstitial Keratitis attacks young persons, nearly all of whom, as was first pointed out by Hutchinson, can be shown to be the subjects of hereditary syphilis, and who present some or all of the following physiognomical characters:—a depressed bridge of the nose, scars at the angle of the mouth, and notched and peg-shaped central upper incisor teeth. The disease affects both eyes, one generally some time before the other. It begins by the appearance of cloudy spots in the cornea, which spread until the whole cornea has a ground-glass appearance, not uniform throughout but with denser

[1] The term "ophthalmia" is now limited to conjunctival inflammations.

opacities here and there. The corneal surface is "steamy." The ciliary zone of vessels, immediately round the cornea, is congested, and iritis is a frequent complication. As a rule pain and photophobia are not great. The cornea seldom clears in less than a year, and even then only imperfectly. Internally, minute doses of mercurials, or where there is decided struma the syrup of the iodide of iron should be given. Locally, atropine should be used to prevent iritis. As the cornea clears, some stimulant, as the dusting of fine calomel powder, may hasten the absorption of the exudation.

Phlyctenular Ophthalmia occurs in strumous or weakly children, especially after hooping-cough or measles. There is great intolerance of light, the slightest attempt to separate the lids causing a gush of tears. The patient is generally kept in bed in a dark room and buries his head in the pillow to exclude the light. The conjunctiva is reddened generally, but spots of localized congestion are seen near little greyish or yellowish elevations on the conjunctiva, or on the cornea near its margin. These papules or pustules may succeed each other in crops for a long time. On the cornea they give rise to vascular ulcers, which may be single or so numerous as to constitute a condition of pannus. As they heal the vessels shrink, and a small white speck is left to mark the seat of the ulcer. As regards treatment, the patient must have a shade or dark glasses, and be sent out of doors daily when the weather permits. Tonics and nourishing food are required. Locally, so long as the secretion is watery atropine must be used; later, mild astringent lotions; and finally, to aid the healing of the ulcer and clearing of the residual opacities, some mercurial ointment or calomel powder should be applied.

Ulcers of the Cornea.—Ulcers occur under many forms, to which very various names have been given. All the forms have certain symptoms in common with each other and with the above diseases. There is great pain in and about the eye, great intolerance of light (especially in superficial ulcers), and congestion of the ciliary zone. They generally leave an opacity, which greatly interferes with sight if in the centre of the pupil. In *severe inflammatory* or *suppurative* ulceration the above symptoms are well marked; the base of the ulcer is greyish in colour, its edges irregular, and the surrounding cornea infiltrated. It extends superficially and deeply, and may cause hypopyon (pus in the base of the anterior chamber), and even perforation of the cornea, or iritis. The *weak ulcer* has little pain or congestion, and seems simply a loss of substance at one part of the cornea. It causes distorted or multiple images. Its existence is a sign of lowered health, and calls for local stimulation and tonic treatment. The *small central ulcer* of children is a small greyish funnel-shaped spot in the centre of the pupil, with little pain or congestion. It sometimes goes on to abscess, but usually heals quickly. The *senile* or *serpiginous ulcer* is a very serious form. There is great pain and photophobia, and unless treated the ulcer gradually eats its way across the cornea, or extends at its margins so as to isolate the central part of the cornea.

The treatment of corneal ulcers varies very much with the type of disease and with its several stages. In the acute cases the eyes should be shaded, sometimes bandaged; atropine applied locally allays pain; eserine is said to act similarly by reducing tension, and is preferable where conjunctival discharge is aggravated by atropine. The weak ulcer should be touched with a nitrate of silver solution, the senile bathed with a quinine lotion. If the inflammatory ulcer be not checked by atropine, and if hypopyon increase, tension may be diminished by *incising* the cornea at its margin, or through the base of the ulcer (Saemisch), or by performing iridectomy.

Abscess of Cornea may result from injury or ill-health. It begins as a yellow spot in the substance of the cornea, with some surrounding haze. It may become absorbed, or burst forwards and be converted into an inflammatory ulcer, or backwards, giving rise to hypopyon. If hot fomentations and atropine do not check it, it must be treated surgically like the inflammatory ulcer.

Staphyloma of the Cornea is a bulging forward in whole or in part of the new tissue which replaces the cornea after ulceration or sloughing. It has a bluish or greyish colour, and may be slight in amount, or so great as to keep the eyelids widely separated and cause great irritation. When there is no irritation it may be left alone; when it is increasing an iridectomy may check its progress. When it is large and causes irritation the eye may be removed entirely, or in part so as to leave a stump on which to fit an artificial eye.

Conical Cornea occurs principally in young women whose health has been much reduced from some chronic cause. The cornea becomes thinned in the centre, and is slowly bulged forward. The condition, which is easily recognized from the glistening appearance and the conical form of the cornea, causes great myopia, which can be only imperfectly remedied by biconcave lenses obscured except at a small central aperture or slit. In severe cases operation may be of some service.

Keratitis Punctata is usually secondary to some deeper-seated disease, *e.g.*, iritis, choroiditis, or sympathetic ophthalmitis. Minute greasy-looking dots are deposited at the back of the lower part of the cornea, generally arranged as a triangle with its apex upwards. The ocular tension and amount of aqueous humour increase. The treatment is that of the causal disease, usually iodide of potassium or a mercurial, with atropine locally.

Arcus Senilis is a whitish crescent or ring just inside the corneal margin. It is a senile change, a fatty degeneration of the corneal tissue, not necessarily accompanied by fatty degeneration elsewhere. It does not influence the healing of corneal wounds in any way.

Diseases of the iris.

In *Acute Iritis* the iris changes in colour and its fibres lose their definition and look muddy. The pupil becomes small, irregular in outline, and sluggish or immobile when stimulated by light. There is a pink zone of congestion round the cornea (the ciliary zone). The aqueous humour is turbid; it may contain blood, and even pus. There is more or less pain in the eye and temple, which is usually worst at night; there is intolerance of light, great increase in the secretion of tears, and impairment of sight. In most cases lymph escapes from the posterior surface of the iris and fixes its margin to the lens at one or more points, or all round, and may even occlude the pupil. In some cases the exudation is entirely serous and no adhesions are formed (serous iritis). Iritis is one of the symptoms of secondary syphilis; it is caused by rheumatism, by ulcers and diffuse inflammations of cornea, by injuries to the cornea, iris, and lens, and forms part of nearly all cases of sympathetic ophthalmitis. The syphilitic form usually involves both eyes; it produces much exudation and often little yellow nodules, and rarely relapses. Rheumatic iritis is generally serous, unilateral, and recurs frequently. Atropine must be freely applied locally to prevent the formation of adhesions, or to break down such as may have already formed. The temple may be leeched, and opiates given if pain is severe. In the syphilitic forms calomel must be given; in the rheumatic alkalis and colchicum. The eyes must be protected by a shade. Traumatic iritis should be treated by continuous cold and leeching. If it is due to a swollen lens, the latter must be removed. After the disease is past the pupil is frequently irregular from adhesions (synechiæ) of the iris to the lens-capsule. If adhesions have been broken down

small brown specks will be seen in the pupil. The whole free edge (exclusion), or the whole posterior surface (total posterior synechiæ), may adhere to the lens-capsule, and the pupil may be completely covered with a film of lymph (occlusion). These three last conditions are apt to cause secondary glaucoma.

Coloboma of the Iris is a congenital defect in the iris. The defect is always in the lower part, and gives the pupil a balloon shape. It may or may not be accompanied by a similar defect in the choroid and retina.

ases ne ry on.

From the intimate association of their vascular supply, the ciliary body, iris, cornea, sclerotic, and choroid are frequently affected together. Diseases in this region all agree in their tendency to relapse frequently during a very chronic course, and to involve separate patches.

Sclerotitis (episcleritis) forms a low painful swelling, of a peculiar rusty colour, under the conjunctiva in the ciliary region. It lasts for months, with frequent relapses. The subjects of this disease are mostly rheumatic or anæmic women. Internally, iodide of potassium is sometimes useful. If that fail small doses of mercury should be given. Locally, atropine, blistering the temple, or massage of the swelling through the upper lid may be tried.

Irido-cyclitis, inflammation of the iris and ciliary body, is characterized by congested patches of a violet colour in the ciliary region, cloudy areas in the cornea, and attacks of iritis with much plastic exudation. There is great pain and intolerance of light. It relapses frequently, each attack leaving more cloudiness of cornea and more iritic adhesions, till ultimately the sclerotic presents a bluish bulging in the ciliary region (ciliary staphyloma), the cornea is opaque, its curvature irregular, and the sight gone.

Irido-choroiditis resembles a mild attack of iritis; there is little pain or photophobia. Small deposits form on the back of the cornea (keratitis punctata). Recent choroiditis and sometimes opacities in the vitreous may be seen with the ophthalmoscope if the pupil be clear. This also relapses frequently, with the formation of much iritic adhesion, and sometimes of secondary glaucoma. This occurs mostly in delicate young persons, and generally involves both eyes. The treatment consists of atropine locally, disuse of the eyes, and tonics with iodide of potassium internally; only in mild cases is a good result obtained. The iritic exudation is generally too plastic to be absorbed.

Wounds or Diseases in the Ciliary Region are extremely liable to involve the other eye sympathetically. There are two affections of very different moment. In *sympathetic irritation* the eye is tender and irritable, cannot bear a bright light, and is easily fatigued by continued strain of the accommodation, as in reading or other close work. This condition usually yields speedily when the other eye is removed, which should be advised without hesitation. *Sympathetic inflammation* is of much more serious moment. It may begin quite insidiously, or with acute pain and intolerance of light. Once begun, it becomes an independent disease, little influenced by treatment directed to the exciting eye, and usually ending at last in irreparable blindness. The symptoms are deposits on the back of the cornea (keratitis punctata), violet-coloured ciliary congestion, often great tenderness of the ciliary region, the iris muddy and in severe cases buff-coloured, and with many large blood-vessels on its surface. Extensive iritic adhesions form which cannot be absorbed. The process is an irido-cyclitis or irido-choroiditis. It may be set up two months or many years after the injury; the eye is never safe. Treatment must evidently be mainly preventive. All blind eyes liable to cause sympathetic inflammation should be at once removed. If some vision be left in the wounded eye, and the patient can be kept under observation, it may be left,—the patient being warned of the danger to the other eye. The inflammation once arisen, the exciting eye, if blind, must be removed; but not if there be any sight in it, as it may be eventually the better eye of the two. The patient must be kept in a dark room and not allowed to use his eyes. Atropine solution must be applied locally. After the inflammation is quite quiescent removal of the lens with a portion of the iris may be of use in giving an artificial pupil.

Diseases of the crystalline lens.

Cataract.—Cataract is an opacity of the crystalline lens. It is due to some alteration in the structure and relationship of its fibres, as the result either of some senile change or defect of development, of local interference with its nutrition (as in glaucoma), of some general diseases such as diabetes, or of local injury to the lens or its capsule. For practical purposes all cataracts are classified under three categories. (A) They may be *hard* or *soft*; below the age of thirty-five, and in diabetes of any age, cataracts are soft. (B) They may be *general* or *partial*, according to the amount of lens involved in the opacity. General cataract may be nuclear (beginning from the centre) or cortical (spreading inward from the periphery); or both conditions may coexist. Partial cataract may be (1) *lamellar*, where one or several of the concentric layers in an otherwise transparent lens becomes opaque. This form is often congenital. It is said to be frequently caused by infantile convulsions. (2) *Pyramidal cataract* is a small white spot on the lens-capsule in the centre of the pupil. This is the result of corneal perforation in purulent ophthalmia. The cornea falls against the lens-capsule when the aqueous humour is evacuated, and becomes adherent to it. The aqueous, refilling after the healing of the perforation, tears away the cornea and leaves the spot of lymph on the capsule. (3) In *posterior polar cataract* the opacity begins at the posterior pole of the lens. It indicates deep-seated disease. (C) Cataract may be *primary* or *secondary*, according as it arises in an eye otherwise healthy or depends on some other disease in it. Cataracts arising from injury to the lens are called *traumatic*.

Symptoms and Treatment of Cataract.—Vision becomes gradually impaired. If the cataract be small and central, vision improves in a dull light or when the eyes are shaded. On ophthalmoscopic examination (see below) the opaque parts appear either as dark striæ converging towards the centre or as a dark central mass. The fundus, if visible, appears red. An attempt should be made to ascertain if it is healthy. On oblique illumination by a convex lens the opaque parts now appear white and the rest of the pupil black. When the cataract is ripe the pupil is filled by a homogeneous pearly-white or amber-coloured opacity. The rest of the eye is healthy if the pupil reacts to light, and the patient can tell the direction of a candle-flame at four feet distance. As a palliative atropine may be used if it be found to improve vision. To remove the cataract operation is required. Operation is undesirable in pyramidal, secondary, and immature cataract, and usually if, while the cataract in one eye is ripe, the other eye remains good, unless the patient specially desires the operation.

The Operation.—In the *soft* cataract of infancy, youth, and diabetes the needle operation should be chosen. The pupil having been dilated by atropine, a fine needle is passed through the cornea near its margin, and lacerates the lens-capsule freely. The lens, acted on by the aqueous humour, swells up and gradually dissolves,—the process of solution taking from two to three months, and generally needing one or two repetitions of the needling. In *hard* cataracts the lens must be extracted entire. The following is the most usual operation. With a narrow knife an incision is made through the upper part of the cornea at its junction with the sclerotic, in length somewhat less

than half the corneal circumference. A portion of iris is drawn through the corneal incision and cut off (iridectomy). Then the lens-capsule is lacerated by a needle. The lens is forced out of the eye by gentle pressure on the sclerotic below. All fragments of lens-substance are carefully removed, the edges of the incision are brought together, the eyes bandaged, and the patient kept in bed for a few days. Ninety-five per cent. of the cases do well, the others going wrong from hæmorrhage into the eye, iritis, or suppuration of the eye. In *lamellar* cataract two courses are open. If dilatation of the pupil by atropine enables the patient to see clearly, the removal of a portion of iris (artificial pupil) will be sufficient; if not, the solution of the lens must be effected by the needle operation. In *traumatic* cataract the pupil is kept dilated by atropine to prevent iritis. If severe iritic or glaucomatous symptoms arise an incision must be made in the cornea, and the softened lens removed along a grooved scoop or by suction.

After the cataract is removed strong convex glasses must be worn for near vision and a somewhat weaker pair for distant vision. Their use must not be allowed till at least two months after the operation.

Dislocation of the Lens may arise from a blow or spontaneously. The lens may pass into the anterior or posterior chamber. If in the posterior chamber it may be invisible, but the iris will be tremulous and the refraction very hypermetropic. If the dislocation be partial the edge of the lens may be seen with the ophthalmoscope as a dark curved line. The lens generally becomes opaque. It may, and often does, cause glaucoma.

Glaucoma.

Glaucoma is a most serious disease, characterized in all its forms by increased tension of the eyeball, impairment of sight, and ultimate irremediable blindness. Its course is usually chronic, lasting sometimes many years; sometimes absolute blindness comes on in a few hours or days.

In the chronic form the earliest symptoms are rapid onset of presbyopia, making it necessary to change the spectacles frequently, and attacks of mistiness of sight, during which artificial lights appear surrounded by coloured rings. Gradually sight is impaired and the field of vision contracted. The pupil is dilated and sluggish; the cornea may be "steamy" and insensitive, the anterior chamber shallow. Large veins pierce the sclerotic a little way from the corneal margin. The lens may have a greenish hue (hence the name), or may become opaque. The optic disk, if visible ophthalmoscopically, is "cupped" or hollowed, and in advanced cases also atrophied. The retinal vessels bend abruptly in rising over its edge, or in deep cupping seem to have their course interrupted for a short distance. The arteries pulsate either spontaneously or on slight pressure on the eyeball. The tension (ascertained by pressing the eyeball against the floor of the orbit) is variously increased. This form may be painless throughout, and the gradual impairment of vision may lead to the fatal error of a diagnosis of cataract. More usually there are occasional acute attacks. Acute glaucoma comes on suddenly; there is much pain in the eye and temple and congestion of the globe; increase of tension and loss of sight are extremely rapid.

All the symptoms depend on the increased tension of the intraocular fluids. The loss of sight and contraction of the visual field result from compression of the retina and its vessels. Pressure on the ciliary nerve paralyses the iris and the accommodation (hence the presbyopia), and renders the cornea insensitive. The anterior chamber is shallowed by the lens being driven forwards, and the disk is cupped by being driven backwards through the lamina cribrosa, the least resistent part of the sclerotic. The veins of the sclerotic are enlarged in order to relieve the obstructed vasa vorticosa. The explanation of the increase of tension is not yet complete. In most cases it is probably due to deficient removal of fluid. Normally this takes place through the suspensory ligament of the lens, round the free edge of the iris, leaving the anterior chamber at the angle of junction of the iris and cornea. Blocking of any part of this channel (most often at the above angle) would cause increase in the tension. Increased blood-supply is also in many cases a cause. Glaucoma is most common after forty. It may be either primary or secondary to some disease or injury of the eye.

Eserine applied locally has proved useful in some early cases of glaucoma. Iridectomy—that is, the removal of a portion of iris through an incision in the cornea—is the most successful mode of checking the disease. In secondary glaucoma the treatment must be directed to the cause, if it is removable.

Muscæ Volitantes.—The floating bodies, specks, &c., so often complained of are usually of no importance. They occur most frequently in myopic eyes. Pathological *muscæ*, however, depend on the presence of opacities in the vitreous, detectable by the ophthalmoscope. They are of very various sizes and shapes, from large masses, as in recent hæmorrhage, to strings, specks, knotted bodies, or finely sparkling particles (cholesterin), or as a diffuse cloud or haze obscuring the retina. From the rate at which the bodies move an opinion may be formed of the fluidity of the vitreous. Disease of the vitreous is usually secondary to disease of some of the surrounding parts, as in high degrees of myopia, in hæmorrhagic and syphilitic choroiditis and retinitis, and diseases of the ciliary region. Hæmorrhage is frequent after blows on or wounds of the eye.

Disseminated Choroiditis is usually a symmetrical disease, arising from acquired or inherited syphilis. There are no characteristic symptoms, but the ophthalmoscope shows in the early stage (rarely observed) yellowish patches (of exudation), over which, unless obscured by haze, the retinal vessels are seen to pass. Later, when the exudation gives place to atrophy, white patches are seen of various sizes with masses of black pigment on or around them, distributed irregularly over the choroid. The retinal vessels may be seen to pass unaltered over some of the white areas. Sometimes the patches of atrophy involve merely the superficial layers and expose the deeper larger choroidal vessels. Vision is impaired, especially if the yellow spot is involved. The treatment is that for syphilis, with rest and protection of the eyes from light. This at least helps to prevent fresh accessions of the disease if it cannot restore the atrophied choroid. Similar spots are seen in non-syphilitic subjects, probably as the result of choroidal hæmorrhage.

In myopia the choroid is frequently atrophied near the disk, especially at its outer edge, forming what is variously known as "posterior staphyloma," "myopic crescent," or "sclerotico-choroiditis posterior." This posterior staphyloma varies much in shape, sometimes surrounding the disk, sometimes limited to the yellow spot, causing then greatly impaired central vision.

Tubercles are sometimes deposited in the choroid, appearing as small yellow spots. Their presence may be of assistance in forming a diagnosis of tubercular disease.

Rupture of the Choroid from injury is generally seen as a long curved line of atrophy with the concavity towards the disk.

Coloboma of the choroid is a congenital defect, indicated by a large white patch of atrophy at the lower part, often embracing the disk,—the surface of the sclerotic often looking uneven. It may exist independently of similar defect in the iris.

Sarcoma of the Choroid is a malignant tumour, usually

pigmented, which tends to destroy the eye, to spread along the optic nerve, and to cause metastalic deposits elsewhere in the body. It causes defect of sight, and if the media are clear may be seen by the ophthalmoscope. It often causes glaucoma and cataract. The tumour must be excised with as much of the optic nerve and orbital tissue as can be reached.

Diseases of the retina.

Detachment of the Retina is a separation of the retina from the choroid by an effusion of serum or of blood, or by the growth of a tumour between them. It occurs most frequently in myopia and from blows on the eye (also from dislocation of the lens and in albuminuria). The detachment varies greatly in extent; it is most usually situated at the lower part of the retina. It causes blindness on the corresponding opposite part of the visual field. With the ophthalmoscope, instead of the red appearance, a greyish reflexion is seen, generally uneven on the surface, with the retinal vessels, reduced in size and dark in colour, coursing over it. The grey surface may be seen to undulate with movements of the eye. Treatment is generally unsatisfactory. Myopic cases should avoid stooping and strain of the eyes to prevent its extension.

Embolism of the Central Artery of the Retina is a plugging of this vessel by a small body, usually detached from one of the valves of a diseased heart. The eye becomes suddenly blind, and on ophthalmoscopic examination the red reflex is found to be replaced by a diffuse white mist, except at the yellow spot where a "cherry-red" spot appears; and the retinal vessels are often reduced to mere threads. After a time the haze passes off the retina, but an atrophied disk and narrowed blood-vessels are left. Treatment is useless. If the embolism is impacted in one of the branches of the retinal artery these appearances will be localized, and a blind spot will correspond to the affected area.

Albuminuric Retinitis occurs in an advanced stage of chronic Bright's disease of the kidneys, usually when the general health has become much impaired. It is especially associated with the granular kidney, and is not seldom the first indication of this serious disease. It causes defective sight, and some of the following characteristic ophthalmoscopic appearances. In the early stage (rarely observed) a greyish haze presents itself at the centre of the retina (from the presence of an albuminous fluid); later, pearly-white sharply-defined spots of various sizes appear, often grouped round the yellow spot (due to fatty degeneration of the coagulated albumen and nerve-fibres). With these there may be found many small hæmorrhages, or a condition of optic neuritis. Vision is seldom completely lost, and may, except in the severest cases, be expected to improve somewhat, especially in the albuminuria associated with pregnancy. Its treatment is that of its cause.

Syphilitic Retinitis is usually a symptom of the secondary stage, affecting both eyes, and producing dimness of vision and night-blindness. Ophthalmoscopically the disk appears hazy, the vessels full and tortuous, the retina also hazy or showing white misty patches, especially near the yellow spot. It is much benefited by a mercurial course.

Hæmorrhagic Retinitis is indicated by the appearance all over the retina of small flame-shaped hæmorrhages with dilated veins. It is perhaps due to gout (Hutchinson).

Hæmorrhages may result from vascular degeneration. They seriously damage sight if they occur at the yellow spot.

Pigmentary Retinitis is a peculiar chronic disease affecting both eyes symmetrically. It is either congenital or begins early in life and advances gradually till it produces complete blindness. Its cause is not well known. It is strongly hereditary, occurring often in several members of one family; it has been found also in the descendants of parents nearly related to each other, and it is common among deaf-mutes. In many cases no cause can be assigned. Its earliest symptom is an inability to get about in the dusk (night-blindness). Then follows a gradual contraction of the field of vision, the patient feeling as if he looked through a tube, seeing objects clearly within his field in good daylight, but nothing beyond. Eventually this central vision also fails. The ophthalmoscopical appearances are symmetrical in both eyes, and are equally characteristic. At the periphery of the retina masses of black pigment are distributed in an irregularly reticulated or lace-like manner over the retina and along the retinal vessels. The disk is pale and "waxlike," and the retinal vessels are much contracted,—it may be, reduced to mere threads. As the visual field contracts the retinal pigment approaches the disk. Treatment is of little use. Galvanism has lately been recommended.

Glioma of the Retina is a tumour of excessive malignancy, arising in the retina and rapidly filling the eye, and spreading from the eye along the optic nerve to the brain, or through the sclerotic to the orbit. It occurs in young children. Thorough and early removal of the eye with the optic nerve may prevent its recurrence.

Diseases of the optic nerve, retina, &c.

The optic nerve may be inflamed in any part of its course, within the skull, in the orbit, and within the eye. To the physician the most important of these inflammations is that of the intraocular end of the nerve or papilla, known as *Optic Neuritis* or *Papillitis* (choked disk), on account of its frequent association with tumour of the brain, of which it is one of the most diagnostic symptoms. The signs may be well marked to the ophthalmoscope before there is the slightest impairment of sight. At first the disk is seen swollen, reddened, its edge indistinct, and the veins distended and tortuous. Later, the swelling of the disk increases, obscuring the disk itself, and extending beyond its edge. The surface has a greyish appearance, streaked with reddish lines, which are enlarged blood-vessels. The retinal arteries and veins at their commencement are obscured by the exudation; at the edge of the swollen disk they bend downwards to reach the retina, over which they pursue a tortuous course, the veins being much distended. Small hæmorrhages are often seen on the disk and retina. All traces of the exudation may pass away. More usually the disk becomes atrophied, of a pale-white colour, with an indistinct margin and shrunken retinal vessels.

Papillitis of both eyes sometimes also arises from lead-poisoning or anæmia. Papillitis of one eye, with subsequent atrophy, is generally due to local injury to the nerve.

Atrophy of the Optic Nerve is sometimes primary, *i.e.*, arises without previous neuritis. In this case the disk becomes gradually of a pale-white or pale-greyish colour, its edge more than usually distinct, and the vessels may not be contracted. Primary atrophy of the optic nerve is one of the most marked symptoms of locomotor ataxia. Many of the cases where no cause is ascertainable are undoubtedly precursory to the usual symptoms of ataxy. Vision always suffers in this form more or less.

Atrophy of the disk may be secondary to glaucoma, neuritis, pigmentary retinitis, and some forms of choroiditis. When unilateral it may be due to embolism, or, if it follow an injury to the head, to fracture of the optic canal, or to a retrobulbar neuritis.

Amblyopia, Amaurosis, &c.—Amblyopia means defective sight; amaurosis, blindness without sufficient obvious cause. Such defective sight is not uncommon in a squinting eye, or one of a different refractive power from its fellow. *Tobacco amblyopia* occurs in adults from excessive tobacco-smoking, especially when combined with alcoholic excess. There is loss of visual acuteness, as tested by read-

ing, of one-fifth to one-tenth, and green and red blindness in the centre of the field. The disk may be normal or have a muddy colour. It usually recovers under abstinence from smoking and alcohol and the use of small doses of strychnia.

Hemianopsia means loss of one-half of the visual field. It is generally bilateral and affects corresponding halves of the two retinæ, *e.g.*, the two right halves or the two left; rarely the two inner halves or the two outer are involved. The dividing line is usually vertical, or nearly so, bending so as to avoid the fixation point. It is due to some disease of the brain, or of one optic tract. (It will be remembered that each optic tract divides at the optic commissure, and supplies one-half of each retina, the right tract going to the right halves, the left to the left.)

Night-blindness without organic change may be due to exposure to bright sunlight, sleeping in moonlight, or to scurvy. Snow-blindness is a similar condition, with congestion of the eyelids and intolerance of light.

rs of c-

In *Hypermetropia* parallel rays falling on the eye meet in a point behind the retina. This is due in most cases to shortening of the axis of the eye (axial hypermetropia), in rarer cases to absence of the lens, and is the physiological condition, after the age of fifty-five, of all previously normal eyes, owing to diminution of the refractive power of the lens. Clear vision is obtained only when the entrant rays are focused on the retina. In the hypermetropic eye this is effected by increase in the refractive power of the lens by the action of the ciliary muscle. In slight hypermetropia this is easily accomplished, and no complaint may be made. In higher degrees the continuous severe strain on the accommodation in reading and other fine work gives rise to aching, watering, and mistiness of the eyes (accommodative asthenopia). These symptoms may first appear after an exhausting illness or prolonged strain of the eyes,—in both cases from reduction of the tone in the ciliary muscle. Convergent squint is a common symptom. In the highest degrees, where no amount of accommodation gives distinct vision, the attempt is given up, and no complaint made. In most cases the continuous use of the accommodation produces a spasm of the ciliary muscle, which renders some of the hypermetropia "latent," what remains being the "manifest" hypermetropia. Both together constitute the "total" hypermetropia. To ascertain the hypermetropia place the patient 20 feet from Snellen's test-types. If a weak convex lens makes sight no worse try stronger and stronger glasses till the best vision is obtained. This gives the "manifest" hypermetropia. If there be no improvement with convex glasses the hypermetropia may be all latent. Paralyse the accommodation by putting a drop of atropine solution and test the "total" hypermetropia. For the ophthalmoscopic tests, see below. Children with asthenopia should wear constantly glasses which nearly correct the hypermetropia. For adults it is not usually necessary to wear glasses for distant vision. For reading the manifest hypermetropia should be corrected, the strength of the glasses being increased as often as asthenopic symptoms reappear.

In *Myopia* or *Short-sight* the retina lies behind the focal point of parallel rays entering the eye; it will therefore be at the conjugate focus of some point at a definite distance from the eye,—its "far point." Objects beyond this point are seen indistinctly. Within this point and up to the "near" point objects are distinctly seen. Myopia is generally dne to elongation of the posterior part of the eye, the sclerotic and choroid at the macula being thinned and bnlging backwards. In severe cases the bulging is general, thinning all the coats and enlarging the eye. Myopia is highly hereditary. It rarely begins before seven, and rarely advances after twenty-five. It is always aggravated, and may be prodnced, by nsing the eyes on fine work, especially in a bad light and in a stooping position. Myopia results also from increased curvature of the cornea, as in interstitial keratitis and conical cornea.

The symptoms of myopia are well known. Distant vision is indistinct, and fine work or printed type is held near the eyes. In high degrees after reading for a time the letters seem to be blurred and to run into each other, while the eyes ache and water owing to inability of the internal recti to keep up the necessary convergence (muscular asthenopia). *Divergent squint may be present.* The eyes are often kept half shut (hence the name "myopia") to exclnde the excess of light. Ophthalmoscopic examination often shows the "myopic crescent" at the outer side of the disk, or all round it, or at the macnla. The other tests are described below. As regards treatment, all myopics should work in a good light, and not in a stooping position. If desired, concave lenses may be given for distant vision. For near vision in high myopia concave lenses not fully corrective may be given, to enable the patient to hold his work at a greater distance and to avoid stooping. If there is mnscular asthenopia prisms with their bases inwards may be used to relieve the strain on the internal recti. Myopic eyes are liable to various affections,—muscæ volitantes, opacity and fluidity of vitreous, choroidal hæmorrhage, and detachment of retina.

Astigmatism is either regular or irregular. *Regular astigmatism* is due to the fact that the surfaces of the cornea and lens are not segments of spheres. The principal abnormality is in the cornea, and it is found that the meridians of greatest and least curvature (the principal meridians) are always at right angles to each other, and that the intermediate meridians pass by regular gradation from the one to the other. It is evident that rays of light from a point passing through the plane of greatest curvature will have met before those passing through the plane at right angles to it, which will form a line, that similarly the first set of rays will have crossed and will in their turn form a line by the time the second have reached their focus, and that between these two points the image will be circular or oval, but blurred. In no case will the image be a point, and hence vision will never be distinct. If one of the principal meridians be emmetropic the astigmatism is "simple"; if both be either hypermetropic or myopic it is "compound"; if one be hypermetropic and the other myopic it is "mixed."

If spherical lenses do not raise the sight of otherwise healthy eyes to the normal standard astigmatism is probable. On ophthalmoscopic examination the disk will be found oval, and altering its shape when the lens is removed from the eye; with the direct method the vessels are not seen with equal distinctness, and may pass across the field in the two principal meridians in the same direction but at different rates if the astigmatism be compound, in opposite directions in "mixed" astigmatism. If the patient look at an arrangement of radiating lines of equal thickness he will not see them all with equal distinctness. Astigmatism is corrected by neutralizing the inequality of the refractive surfaces by means of cylindrical lenses. In many cases the vision cannot be brought up to the normal standard.

There are many ways of estimating astigmatism. One method is to find by the test-types the spherical lens which gives the best distant vision; then, by means of a narrow slit in a metal disk, to find the plane in which vision is further most improved. Spherical lenses are placed in front of this slit till the one which gives the best attainable vision is found; this gives the cylindrical lens necessary for this plane. A similar inquiry is conducted with the plane at right angles to this. Spectacles are ordered compounded of the spherical lens and the two cylindrical lenses with their axes at right angles to each other.

Irregular astigmatism depends on irregularities in the surface of the cornea or in the refractive power of the lens. It can seldom be remedied.

Disorders accommodation.

Presbyopia.—From ten years onwards the "near" point of the eye gradually recedes, owing to increasing firmness of the lens and probably diminishing power in the ciliary muscle. Presbyopia has been arbitrarily fixed as commencing when the near point recedes to 9 inches, because then discomfort in reading is generally complained of. In normal eyes it begins about forty, in hypermetropia earlier, and in myopia later. There is no increased difficulty in seeing distant objects, but ordinary type has to be held inconveniently far away. The treatment consists in giving glasses to enable the patient to read at 9 inches. In practice it is usually sufficient to enable him to read at 12 inches' distance. As age advances the presbyopia increases, and it is necessary from time to time to increase the strength of the spectacles.

Paralysis of the Accommodation is not uncommon after diphtheria; it forms one of the symptoms of paralysis of the third nerve.

Spasm of the Accommodation is common in hypermetropia, and is sometimes present in the opposite condition of myopia.

Strabismus or squint.

In strabismus the two eyes are not directed to the same point in space. The deviation may be inwards or outwards, downwards or upwards,—the first two forms being by far the most common. *Inward* or *Convergent Strabismus* is due either (1) to paralysis of the external rectus muscle or (2) to over-development of the interni. (1) *Paralytic convergent squint* is the result of some affection of the sixth nerve or its nerve-centre, owing generally either to syphilis or to nervous exhaustion. It varies in amount from slight weakness to complete paralysis of the muscle. When the paralysis is complete the eye is turned inwards and cannot be moved outwards beyond the middle of the fissure of the eyelids. In minor degrees, where the deformity is not so evident, it may be difficult to tell which is the squinting eye. If the patient be told to look at an object held a short distance in front of him and a piece of ground glass be placed before the squinting eye, neither eye will move; if the sound eye now be covered the squinting eye will turn outwards to fix the object, while the sound eye will move a greater distance inwards; the "secondary" is greater than the "primary" squint. The reason of this is that the nerve to the paralysed externus and that to the sound internus of the other eye, which work together, both receive the same stimulus from the will, and that the sound muscle acts more strongly than the other. Owing to the displacement of the yellow spot double vision is produced, the false image being projected towards the side of the paralysed muscle (homony-

mous diplopia). The diplopia is always most distressing, and may cause giddiness when the strabismus is slight. The treatment consists in the use of iodide of potassium in the syphilitic, and in nervine tonics in the neurasthenic cases. The muscle may be faradized to keep up its tone. In bad cases tenotomy of the internal rectus may be necessary. The squinting eye may be covered to prevent the diplopia. (2) *Convergent strabismus from over-development of the internal recti* ("concomitant" strabismus) is almost always due to hypermetropia. Its production depends on the intimate relation between accommodation and convergence, every degree of the one evoking a constant quantity of the other, so that normally the two eyes are converged upon the object accommodated for. In hypermetropia clear vision needs an excess of accommodation which in its turn produces an excess of convergence, so that the two eyes meet in a point nearer than that looked at; they squint, in short. The eyes may squint only during accommodation for a near object (periodic squint), but generally the internal recti become so developed as to produce a constant convergence. If either eye is used indifferently for vision the squint is "alternating." Generally one eye is habitually used, the sight in the other eye becoming defective. The amount of squint bears no ratio to the amount of hypermetropia, being frequently absent in the higher degrees where accommodation fails to give clear sight and is not exercised. Double vision does not occur, because the image of the squinting eye is unconsciously suppressed.

In periodic squint glasses to correct the hypermetropia ought to be given. For permanent squint division of the tendons of one or both internal recti muscles is necessary. The operation diminishes the power of these muscles by allowing them to become attached to the globe farther back. Care must be taken not to produce too great an effect, it being preferable rather to leave a little convergence.

In rare cases myopia is associated with convergent squint.

Divergent Strabismus arises from weakness of the internal rectus, as in myopia. In the condition known as muscular asthenopia it is present only after a prolonged effort of convergence. It arises also where the sight is defective, as with corneal opacities, or from unskilful operation for convergent squint. It can generally be improved by tenotomy of the external and "advancement" of the internal rectus muscle.

In paralysis of the superior oblique muscle the deviation is slight. Owing to interference with the movement downward and outward, double vision is present when the eyes are directed below the horizontal line.

Paralysis of the Third Nerve causes ptosis, loss of accommodation, and dilatation of the pupil, and the eye can be moved *only slightly* downwards and outwards. All the branches are seldom affected alike.

Diseases of the eyelids.

Ophthalmia Tarsi (blepharitis) is a chronic inflammation of the follicles of the eyelashes and their glands, attacking strumous children, especially after measles. The edges of the lids are covered with small scabs, which gum the lashes into pencils; when the scabs are removed small freely-bleeding ulcers are exposed. The conjunctiva is also reddened. Eventually the lashes either fall out or become misdirected, the border of the lids looks thickened and bald, and the eyes continually water from eversion of the orifice of the tear-duct. The scabs must be removed daily by means of an alkaline lotion, and a weak mercurial ointment applied to the lids. In bad cases the lashes must be pulled out, and the ulcers touched with nitrate of silver.

A *Stye* is an abscess in a Meibomian gland, or in the cellular tissue of the lid. Styes are apt to occur in crops, and generally point to some derangement of health. They should be poulticed till the matter points, then opened with a lancet. Tonics are needed internally.

Chalazion is a cyst in a Meibomian gland. It forms a small peasized painless swelling under the skin of the lid. It should be opened from the conjunctival surface and its contents expressed.

Epithelioma (rodent ulcer) occurs in old people, grows slowly, forming a hard irregular mass, with an ulcerated surface covered by scabs; it may extend in all directions, destroying the tissues it reaches. The treatment consists in complete removal by the knife or chloride of zinc paste.

Diseases of the lacrymal apparatus.

The lacrymal gland sometimes suppurates, and must be treated like any other abscess. Most of the diseases of this system arise in the punctum, canaliculi, lacrymal sac, or nasal duct, and all cause overflow of tears on the cheek. The punctum may be everted, from disease of the conjunctiva, paralysis of the facial nerve, or the dragging of a scar in the cheek. The canaliculus may be constricted or obliterated. The nasal duct may be obstructed from chronic disease of its mucous membrane or bony wall. The result of this is the retention of tears in the lacrymal sac, then the formation by distension of this sac of a small tumour at the inner angle of the eye, from which first clear mucus, and possibly, at a later period, also pus may be pressed back into the eye. Finally, if the case is neglected an abscess may form which may burst externally and cause a troublesome fistula. The treatment in the first place must be the dilatation of the stricture. The canaliculus is first slit on its conjunctival surface along its whole length, then successively larger probes are passed through the stricture. Abscesses when formed must be opened, and when inflammation has subsided the stricture dilated. The sac may be washed with astringent solutions. When the stricture is due to bone-disease its cure is not hopeful.

Injuries of the eyeball.

Blows may rupture the coats of the eye,—the sclerotic and underlying coats being generally injured. Hæmorrhage takes place between the coats and into the chambers of the eye. The eye may be removed at once; if any perception of light remain, the excision should be delayed to see if there be any chance of the eye being saved. Usually the eye shrinks and becomes quite useless.

Blows may cause damage to the interior of the eye without injuring the outer coats. There may be hæmorrhage into the anterior or the posterior chamber,—the latter a most serious condition, seldom completely recovered from. The choroid may be ruptured, the lens dislocated, or the iris torn from part of its ciliary attachment; and the retina is not seldom detached from the choroid.

Wounds.—Small foreign bodies—bits of steel, &c.—are often impacted in the cornea. They should be removed as soon as possible, as they give rise to great pain, and may seriously injure the cornea. If there is much after-irritation atropine should be used freely to the eye.

Burns with caustic alkalis and acids or molten lead are common. When seen the whole conjunctiva should be carefully freed from all of the irritant. If lime has been the cause, a weak acid lotion should be used. Then oil should be dropped into the conjunctival sac, and any inflammatory symptoms treated as they arise. If the epithelial layer of the cornea only has been destroyed, it often clears to a wonderful extent; but deeper injuries may cause severe ulcerative inflammation of the cornea, and the conjunctiva may slough in part, with ultimate formation of a scar binding the lid to the eye (symblepharon).

Penetrating Wounds.—Such wounds of the cornea and sclerotic, if only the foreign body be *not* in the eye, generally do well. Usually some of the deeper structures are involved, and these cases are always very serious. The eye may be rapidly lost from general inflammation, or if not it may become completely blind. In almost any case, especially where the wound is in the ciliary region, the other eye is apt to be sympathetically involved. If the injured eye therefore is blind, and if there is inflammation in the ciliary region, it must be at once excised. If the eye be not blind, the ciliary region quiet, and no foreign body in the lens or vitreous humour, the eye may be preserved,—the danger of involvement of the other eye being put before the patient. In such cases it is impossible to lay down any general rules. Each case must be judged on its own merits by the ophthalmic surgeon.

Use of the Ophthalmoscope.

Use of the ophthalmoscope.

The ophthalmoscope consists of a small mirror with a small aperture in the centre. Most instruments have now in addition a series of concave and convex lenses arranged on a disk so that they can be brought successively behind the central perforation. A large lens of about 3-inch focus is also required.

Rays of light entering the eye in any given direction are reflected by the choroid along the same direction. Ordinarily, therefore, the fundus cannot be seen, because an eye so placed as to see the emerging rays intercepts the entrant ones. The ophthalmoscope, by placing the source of light in front of the observer's eye, enables it to see and examine the interior of the other eye.

There are two methods of examination,—the indirect and the direct. (1) The *indirect* method, which forms a real, inverted, and slightly magnified image in front of the observed eye, may be illustrated thus. Place a convex lens of 2-inch focus in front of this page, and let these represent crystalline lens and retina respectively. Place now a second similar lens in front of the first, and the print will be seen inverted and slightly magnified. (2) The *direct* method forms a virtual, erect, much magnified image. Place one of the above lenses within 2 inches of the page and your own eye close to it. The letters will appear erect and enlarged.

To use the ophthalmoscope,—place the patient in a dark room, with a lamp to one side of and a little behind the head. If the indirect method is to be employed, sit in front of the patient, with the mirror in your right hand before your right eye, the large lens in your left. Reflect the light from a distance of about 2 feet into one of the eyes, and when you see a red reflexion place the lens in front of it, and you will obtain the inverted image of the fundus. (A) Begin your examination with the optic disk by telling the patient to direct the observed eye a little inwards. Note the following points:—(*a*) the colour of the disk, normally a yellowish pink, but varying considerably owing to tint of surrounding choroid, &c.; (*b*) a paler spot in its centre, which may be due to the funnel-shaped expansion of the nerve, the *physiological cup*; (*c*) the distinctness of the edge (spots of black pigment here are of no importance); (*d*) when the lens is removed from the eye the image of the disk remains of the same size if the eye is emmetropic, becomes smaller if the eye is hypermetropic, and larger if it is myopic, and alters in shape if there is astigmatism. (B) The retinal vessels appear as

red lines, the arteries paler and about two-thirds the size of the darker veins. They arise in the centre of the disk, run usually in pairs, branching as they pass over the retina. Note their light central streak, their amount of tortuosity, and the presence or absence of white lines by their side. (C) Note the usually uniform redness of the choroid. In light-haired and dark-haired persons the vessels appear as dark or light red bands on the general red ground. (D) The yellow spot is indicated either by a deeper redness of the choroid or by a bright yellow spot surrounded by a shifting white halo.

By the direct method the mirror is used without the large lens,—if necessary, one of the smaller lenses being placed behind the central perforation. (A) Examine the crystalline lens (see "cataract" above). (B) Opacities in the vitreous humour are detected as moving bodies when the eye is moved about and then brought to a standstill. (C) Ascertain the refraction. The eye is ametropic if the vessels are seen distinctly at more than 18 inches' distance. It is hypermetropic if the observer on moving his head finds the vessels moving in the same direction; myopic if they go the opposite way. To measure the amount of ametropia needs practice and power of the observer to relax his accommodation completely. Rays leaving the hypermetropic eye are divergent; to be seen clearly by the observer they must be rendered parallel. The strongest convex lens, therefore, which, placed behind the central aperture, gives a clear image of the fundus is the measure of the hypermetropia. Similarly the lowest concave lens with clear image indicates the amount of myopia. (D) To examine the details of the fundus, the mirror is approached closely to the observed eye.

Retinoscopy.—The observer sitting at a distance of 4 feet from the patient reflects the light into his eye, after dilating the pupil with atropine, and rotates the mirror slightly. A shadow will be seen to cross the pupil,—in myopia of more than 1D ($\frac{1}{40}$) in the same direction as the rotation, in all other cases in the opposite direction. This method is useful in determining and correcting the refraction where the patients are too young or too stupid to assist with their answers. (A. BR.)

OPIE, AMELIA (1769-1853), the wife of John Opie, noticed below, was the daughter of Dr Alderson, a physician in Norwich, and was born there in 1769. The circumstances of her early life gave the bent to her after-career. In her girlhood she beguiled the solitude of her father's summerhouse by composing songs and tragedies; on her visits to London the superior society into which the accomplishments of her mind and the graces of her person introduced her served to stimulate her aspirations; and after her marriage in 1798 she was encouraged by her husband to become a candidate for literary fame. Accordingly, in 1801 she published a novel entitled *Father and Daughter*. Although this tale showed no artistic ability in dealing either with incidents or with characters, yet it was the work of a lively fancy and a feeling heart, and speedily brought its author into notice. She was encouraged to publish a volume of sweet and graceful poems in 1802, and to persist in the kind of novel-writing which she had so successfully commenced. *Adeline Mowbray* followed in 1804, and *Simple Tales* in 1806. The death of her husband in 1807 and her return to Norwich did not slacken her industry. She published *Temper* in 1812, *Tales of Real Life* in 1813, *Valentine's Eve* in 1816, *Tales of the Heart* in 1818, and *Madeline* in 1822. At length, in 1825, her assumption of the tenets and garb of the Quakers checked her literary ardour and changed her mode of life. Beyond a volume entitled *Detraction Displayed*, and several contributions in prose and verse to various periodicals, nothing afterwards proceeded from her pen. The rest of her life was spent in travelling and in the exercise of Christian benevolence. She died at Norwich in 1853. A *Life of Mrs Opie*, by Miss C. L. Brightwell, was published in 1854.

OPIE, JOHN (1761-1807), historical and portrait painter, was born at St Agnes near Truro in May 1761. He early showed a taste for drawing, and for scholarship also, having at the age of twelve mastered Euclid and opened an evening school for arithmetic and writing. Before long he won some local reputation by portrait-painting; and in 1780 he started for London, under the patronage of Dr Wolcot (Peter Pindar), who hoped to win credit, and still more substantial benefits, from the fame of his young protégé. Opie was introduced to the town as "The Cornish Wonder," a self-taught genius. The world of fashion, ever eager for a new sensation, was attracted; the carriages of the wealthy blocked the street in which the painter resided, and for a time he reaped a rich harvest by his portraits. But soon the fickle tide of popularity flowed past him, and the painter was left neglected. He now applied himself with redoubled diligence to correcting the defects which marred his art, meriting the praise of his rival Northcote—"Other artists paint to live; Opie lives to paint." At the same time he sought to supplement his early education by the study of Latin and French and of the best English classics, and to polish the rudeness of his provincial manners by mixing in cultivated and learned circles. In 1786 he exhibited his first important historical subject, the Assassination of James I., and in the following year the Murder of Rizzio, a work whose merit was recognized by the artist's immediate election as associate of the Academy, of which he became a full member in 1788. He was employed on five subjects for Boydell's "Shakespeare Gallery"; and until his death, on the 9th of April 1807, his practice alternated between portraiture and historical work. His productions are distinguished by breadth of handling and a certain rude vigour, individuality, and freshness. They are wanting in grace, elegance, and poetic feeling. Opie is also favourably known as a writer on art by his *Life of Reynolds* in Wolcot's edition of Pilkington, his *Letter on the Cultivation of the Fine Arts in England*, in which he advocated the formation of a national gallery, and his *Lectures* as professor of painting to the Royal Academy, which were published in 1809, with a memoir of the artist by his widow.

OPITZ, MARTIN. See GERMANY, vol. x. p. 530.

OPIUM (ὄπιον, dim. from ὀπός, juice), a narcotic drug prepared from the juice of the opium poppy, *Papaver somniferum*, L., a plant probably indigenous in the south of Europe and western Asia, but now so widely cultivated that its original habitat is uncertain. The medicinal properties of the juice have been recognized from a very early period. It was known to Theophrastus by the name of μηκώνιον, and appears in his time to have consisted of an extract of the whole plant, since Dioscorides about 77 A.D. draws a distinction between μηκώνειον, which he describes as an extract of the entire herb, and the more active ὀπός, derived from the capsules alone. From the 1st to the 12th century the opium of Asia Minor appears to have been the only kind known in commerce. In the 13th century *opium thebaicum* is mentioned by Simon Januensis, physician to Pope Nicholas IV., while *meconium* was still in use. In the 16th century opium is mentioned by Pyres (1516) as a production of the kingdom of Cous (Kuch Behar, south-west of Bhutan) in Bengal and of Malwa.[1] Its introduction into India appears to have been connected with the spread of Islam. The opium monopoly was the property of the Great

1 *Aromatum Historia*, ed. Clusius, Ant., 1574.

Mogul and was regularly sold. In the 17th century Kaempfer describes the various kinds of opium prepared in Persia, and states that the best sorts were flavoured with spices and called "theriaka." These preparations were held in great estimation during the Middle Ages, and probably supplied to a large extent the place of the pure drug. Opium is said to have been introduced into China, probably by the Arabs (1280-95), during the reign of Taitsu, and its use seems to have temporarily ceased in 1368. It appears to have been commonly used in that country as a medicine before the trade with India commenced.[1] In a Chinese herbal compiled more than two centuries ago both the plant and its inspissated juice are described, together with the mode of collecting it, and in the *General History of the Southern Provinces of Yunnan*, revised and republished in 1736, opium is noticed as a common product. Up to this date, however, it was imported in comparatively small quantity by the Chinese solely as a remedy for dysentery, diarrhœa, and fevers, and was usually brought from India by junks as a return cargo. In the year 1757 the monopoly of opium cultivation passed into the hands of the East India Company through the victory of Clive at Plassey. Up to 1773 the trade with China had been in the hands of the Portuguese, but the quantity annually exported to that country rarely exceeded 200 chests. In that year the East India Company took the trade under their own charge, and in 1776 the annual export reached 1000 chests, and 4054 chests in 1790. Although the importation was forbidden by the Chinese emperor Keaking in 1796, and opium-smoking punished with severe penalties, which were ultimately increased to transportation and death, the trade continued and had increased during 1820-30 to 16,877 chests per annum. In 1839 a proclamation was issued threatening hostile measures if the English opium ships serving as depôts were not sent away. The demand for removal not being complied with, 20,291 chests of opium (of 149⅓ lb each), valued at £2,000,000, were destroyed by the Chinese commissioner Lin; but still the British sought to smuggle cargoes on shore, and some outrages committed on both sides led to an open war, which was ended by the treaty of Nanking in 1842 (see CHINA, vol. v. p. 651). From that time to the present, in spite of the remonstrances of the Chinese Government, the exportation of opium from India to China has continued, having increased from 52,925 piculs (of 133⅓ lb) in 1850 to 96,839 piculs in 1880. It appears to be certain, however, that, while the court of Peking was endeavouring to suppress the foreign trade in opium from 1796 to 1840, it did not or could not put a stop to the home cultivation of the drug, since a Chinese censor in 1830 represented to the throne that the poppy was grown over one-half of the province of Chekeang, and in 1836 another, Cho Tsun, stated that the annual produce of opium in Yunnan could not be less than several thousand piculs. At present it is estimated that south-western China, including Szechuen, produces not less than 224,000 piculs, while the entire import from India does not exceed 100,000 piculs. Opium is now produced in nine out of the eighteen provinces of China. The comparative cheapness of the Chinese opium, the lighter duties levied upon it, and the increasing care taken in its cultivation are enabling it to compete successfully with the Indian drug even in eastern China, where, however, it has hitherto been chiefly used to mix with and cheapen the foreign article. A time is confidently anticipated by the Chinese when Indian opium will be entirely supplanted by the native drug. See *Commercial Reports*, China, No. 2 (1881), p. 138.

[1] Mr R. Saunders of Ghazipur suggests (*Pharm. Journ.*, [3], iv. p. 652) that it was introduced from Nepal and afterwards supplied by the Dutch, who purchased the drug for export long before the East India Company held possessions in India.

The amount of opium imported into Great Britain in 1861, 1871, and 1881 was 284,005, 591,466, and 793,146 lb respectively, and the exports for the same years 290,120, 307,399, and 401,883 lb.

Production and Commerce.—Although the collection of opium is possible in all places where there is not an excessive rainfall and the climate is temperate or subtropical, the yield is smaller in temperate than in tropical regions, and the industry can only be profitably carried on where labour and land are sufficiently cheap and abundant; hence production on a large scale is limited to comparatively few countries. The varieties of poppy grown, the mode of cultivation adopted, and the character of the opium produced differ so greatly that it will be convenient to consider the opiums of each country separately.

Turkey.—The poppy cultivated in Asia Minor is the variety *glabrum*, Boissier, distinguished by the sub-globular shape of the capsule and by the stigmata or rays at the top of the fruit being ten or twelve in number. The flowers are usually of a purplish colour, but are sometimes white, and the seeds, like the petals, vary in tint from dark violet to white. The cultivation is carried on, both on the more elevated and lower lands, chiefly by peasant proprietors. A naturally light and rich soil, further improved by manure, is necessary, and moisture is indispensable, although injurious in excess, so that after a wet winter the best crops are obtained on hilly ground, and in a dry season on the plains. The land is ploughed twice, the second time crosswise, so that it may be thoroughly pulverized; and the seed, mixed with four times its quantity of sand, to prevent its being sown too thickly, is scattered broadcast, about ¾ to 1 lb being used for every toloom (1600 square yards). The crop is very uncertain owing to droughts, spring frosts, and locusts, and, in order to avoid a total failure and to allow time for collecting the produce, there are three sowings at intervals from October to March,—the crops thus coming to perfection in succession. But notwithstanding these precautions quantities of the drug are wasted when the crop is a full one, owing to the difficulty of gathering the whole in the short time during which collection is possible. The first sowing produces the hardiest plants, the yield of the other two depending almost entirely on favourable weather. In localities where there is hoar frost in autumn and spring the seed is sown in September or at latest in the beginning of October, and the yield of opium and seed is then greater than if sown later. After sowing, the land is harrowed, and the young plants are hoed and weeded, chiefly by women and children, from early spring until the time of flowering. In the plains the flowers expand at the end of May, on the uplands in July. At this period gentle showers are of great value, as they cause an increase in the subsequent yield of opium. The petals fall in a few hours, and the capsules grow so rapidly that in a short time—generally from nine to fifteen days—the opium is fit for collection. This period is known by the capsules yielding to pressure with the fingers, assuming a lighter green tint, and exhibiting a kind of bloom called "cougak," easily rubbed off with the fingers; they are then about 1½ inches in diameter. The incisions are made by holding the capsule in the left hand and drawing a knife two-thirds round it, or spirally beyond the starting-point (see fig. 2, *a*, p. 790), great care being taken not to let the incisions penetrate to the interior lest the juice should flow inside and be lost. (In this case also it is said that the seeds will not ripen, and that no oil can be obtained from them.) The operation is usually performed after the heat of the day, commencing early in the afternoon and continuing to nightfall, and the exuded juice is collected the next morning. This is done by scraping the capsule with a knife and transferring the concreted juice to a poppy-leaf held in the left hand, the edges of the leaf being turned in to avoid spilling the juice, and the knife-blade moistened with saliva by drawing it through the mouth after every alternate scraping to prevent the juice from adhering to it. When as much opium has been collected as the size of the leaf will allow, another leaf is wrapped over the top of the lump, which is then placed in the shade to dry for several days. The pieces vary in size from about 2 oz. to over 2 lb, being made larger in some districts than in others. The capsules are generally incised only once, but the fields are visited a second or third time to collect the opium from the poppy-heads subsequently developed by the branching of the stem. The yield of opium varies, even on the same piece of land, from ⅓ to 7½ chequis (of 1·62 lb) per toloom (1600 square yards), the average being 1½ chequis of opium and 4 bushels (of 50 lb) of seed. The seed, which yields 35 to 42 per cent. of oil, is worth about two-thirds of the value of the opium. The whole of the operation must, of course, be completed in the few days—five to ten—during which the capsules are capable of yielding the drug. A cold wind or a chilly atmosphere at the time of collection lessens the yield, and rain washes the opium off the capsules. Before the crop is all gathered in a meeting

of buyers and sellers takes place in each district, at which the price to be asked is discussed and settled, and the opium handed to the buyers, who in many instances have advanced money on the standing crop. When sufficiently-solid the pieces of opium are packed in cotton bags, a quantity of the fruits of a species of *Rumex* being thrown in to prevent the cakes from adhering together. The bags are then sealed up, packed in oblong or circular baskets, and sent to Smyrna or other ports on mules. On the arrival of the opium at its destination, in the end of July or beginning of August, it is placed in cool warehouses to avoid loss of weight until sold. When transferred to the buyer's warehouses the bags are opened and each piece is examined by a public inspector in the presence of both buyer and seller, the quality of the opium being judged by appearance, odour, colour, and weight. It is then sorted into three qualities:—(1) finest quality; (2) current or second; (3) chicanti or rejected pieces. A fourth sort consists of the very bad or wholly factitious pieces. The substances used to adulterate opium are grape-juice thickened with flour, fig-paste, liquorice, half-dried apricots, inferior gum tragacanth, and sometimes clay or pieces of lead or other metals. The chicanti is returned to the seller, who disposes of it at 20 to 30 per cent. discount to French and German merchants for the manufacture of morphia. After inspection the opium is hermetically sealed in tin-lined boxes containing about 150 ℔. Turkey opium is principally used in medicine on account of its purity and the large percentage of morphia that it contains, a comparatively small quantity being exported to China.

A number of varieties exist in commerce, differing in certain qualities, and, to a certain extent, in external character. These are generally exported under the names of the districts where they are prepared, but are more generally known in English commerce by the name of the port from which they are shipped. Thus, Constantinople opium includes the produce of Bogaditz, Karahissar Sahib, Kutchaya, Balukhissar, Kurkagatsch, Ghéve, Beybazar, Angora, Malatia, and Tokat, as well as Macedonian opium from Salonica. Smyrna opium comprises opium from Afium Karahissar, Ushak, Akhissar, Tanshauli, Isbarta, Koniyeh, Bulladan, Hamid, and Magnesia, and the Yerli[1] varieties. In English commerce these are roughly divided into shipping, druggist's, and manufacturer's opium.

Shipping opium includes varieties of a pale or yellowish colour internally, of a soft consistence, and free from poppy débris, &c., or "chaff," as it is technically called. Such opium affords a large amount of extract, and leaves very little insoluble residue when dissolved in water, and on this account is preferred in countries where opium-smoking or eating is practised. The principal varieties used for this purpose are Malatia (including that of Kharput), Tokat, Salonica, Balukhissar (including the produce of Kurkagatsch), Bogaditz, and the finest qualities of Angora and Yerli. The chief markets are China, Peru, the West India Islands, British Guiana, and Brazil; and the United States also purchase the same kinds for reshipment.

Druggist's opium includes the varieties purchased for use in medicine in European countries and the United States. It is generally of firmer consistence and rather darker colour than shipping opium. The finest varieties of this kind in English commerce are Beybazar, Yerli, Karahissar (including Adet, Amasia, and Akhissar opiums), "Current" Smyrna, and Angora. Ushak, Yerli, and Karahissar opiums are purchased chiefly for the American market, and the Ghéve or Ismid opium for the Continental.

Manufacturer's opium includes chicanti or low-priced qualities of all varieties, and is used only for the manufacture of morphia. Persian opium is used for this purpose when Turkey opium is dear.

Malatia opium usually occurs in pieces of irregular shape, weighing from 1½ to 3 ℔, and about 1½ to 2 inches thick, the "paste" or substance being soft and pale and remarkably free from foreign matter or "chaff," and the exterior being covered with a bright bluish green leaf; the paste of Tokat is similar, but usually of thinner consistence and darker colour. Bogaditz opium is met with in smaller pieces, usually 2 to 3 oz., and is covered with a yellowish green leaf, the surface being rough with *Rumex* fruit. Occasionally, however, pieces are met with from 1 to 1½ ℔ in weight, still more rarely up to 4 ℔ in weight, approaching more nearly to the Balukhissar and Kurkagatsch varieties, which are usually similar to the Bogaditz, but in larger pieces. Karahissar opium is in rather large conical lumps; formerly the pieces frequently bore the impress of a poppy-head pressed into the top. The Adet, Akhissar, and Amasia opiums are very similar in appearance, and usually pass under the name of Karahissar. Angora opium usually occurs in small pieces carelessly prepared, so as to be rough and unsightly in appearance although of good quality. Occasionally samples of good colour, soft consistency, and excellent quality are met with, and these are always used as shipping opium. Yerli is a fine pasty or gummy opium, with a rough surface and with much *Rumex* fruit adhering to it. Ghéve or Ismid[2] opium is usually in small rounded cakes, weighing about 2 to 3 oz. in weight. The pieces, known in trade as "Constantinople pats," have a smooth shining appearance, with the midrib of the poppy-leaf they are wrapped in forming a median line on the surface. The interior often shows layers of light and dark colour. Yoghourma is a very inferior opium, and, as its name implies, is "remade" or made up at the port of shipment. It is usually sold to morphia manufacturers at a price determined by analysis.

In Macedonia opium culture was commenced in 1865 at Istip, with seed obtained from Karahissar in Asia Minor, and has since extended to the adjacent districts of Kotchava, Stroumnitza, Tikvish, and Kinprulu-veles. The crop in 1882 was 135,000 ℔ of opium and 500,000 to 600,000 ℔ of seed, most of the drug being exported under the name of Salonica opium to Great Britain at prices ranging from 12s. 6d. to 16s. per ℔. Macedonian opium, especially that produced at Istip, is very pure, yielding about 11 per cent. of morphia, and is considered equal to the Malatia produce. The Turkish Government encourage the development of the industry by remitting the tithes on opium and poppy-seed for one year on lands sown for the first time, and by distributing printed instructions for cultivating the poppy and preparing the opium. In these directions it is pointed out that the opium crop is ten times as profitable as that of wheat. Four varieties of poppy are distinguished,—two with white flowers, large oval capsules without holes under their "combs" (stigmas), and bearing respectively yellow and white seed, and the other two having red or purple flowers and seeds of the same colour, one bearing small capsules perforated at the top, and the other larger oval capsules not perforated. The white varieties are recommended as yielding a more abundant opium of superior quality. The yellow seed is said to yield the best oil; that obtained by hot pressure is used for lamps and for paint, and the cold-pressed oil for culinary purposes.

Opium is also grown in Bulgaria, but almost entirely for home consumption; any surplus produce is, however, bought by Jews and Turks at low prices and sent to Constantinople, where it is sold as Turkish opium. It is produced in the districts of Kustendil, Lowtscha, and Halitz, and is made into lumps weighing about 4 oz., of a light-brown colour internally, and containing a few seeds; it is covered with leaves which have not been identified. Samples that have been analysed by Herr Theegarten have yielded from 7 to 19 per cent. of morphia, and only 2 to 3 per cent. of ash, and are therefore of excellent quality.

India.—The poppy grown in India is generally the same as that used in Persia, but in the Himalayas a red-flowered variety with black seeds is met with. The largest amount of opium is produced in the central tract of the Ganges, extending from Dinajpur in the east to Agra in the west, and from Gorakhpur in the north to Hazaribagh in the south, and comprising an area of about 600 miles long by 200 broad. The region next in importance consists of the tableland of Malwa and the slopes of the Vindhya Hills in Indore.

The opium industry in Bengal is a Government monopoly, and the districts are divided into two agencies, Behar and Benares, which are under the control of officials residing respectively at Patna and Ghazipur. In 1883 463,829 acres were under poppy cultivation in the Behar agency, and 412,625 in that of Benares. Any one who chooses may undertake the industry, but cultivators are obliged to sell the opium exclusively to the Government agent at a price fixed beforehand by the latter, which is approximately 3s. 6d. per ℔, the Government selling it at about 11s. per ℔. The peasant is, however, said to be fully remunerated by the price he receives. It is considered that with greater freedom the cultivator would produce too great a quantity, and loss to the Government would soon result. Advances of money are often made by the Government to enable the ryots to grow the poppy.

In Malwa the cultivation is free and extremely profitable, the crop realizing usually from three to seven times the value of wheat or other cereals, and in exceptionally advantageous situations from twelve to twenty times as much. On its entering British territory a heavy duty is imposed on Malwa opium, so as to raise its price to an equality with the Government article. The tax was formerly collected at Indore only, but since other stations have been made at Ujjain, Jaora, and Udaipur the export has increased to 500 chests a month. Malwa opium is shipped from Bombay.[3]

The area under poppy cultivation outside these districts is comparatively small, but it appears to be increasing throughout the plains of the Punjab. The poppy is grown for opium, according to Stewart (*Punjaub Plants*, Lahore, 1869, p. 10), in the valley of the Bias east of Lahore. It is cultivated up to 7500 feet above sea-level, the opium of Kulu in this district being considered of excellent quality. In Nepal, Bashahr, and Rampur, and at Doda Kashtwar in the Jammu territory, opium is produced and exported to Yarkand, Khotan, Aksu, and various Chinese provinces.

The land intended for poppy culture is usually selected near villages, in order that it may be more easily manured and irrigated. On a rich soil a crop of maize or vegetables is grown during the rainy season, and after its removal in September the ground is

[1] The word *yerli* means "grown near," and is applied to opium produced in the immediate neighbourhood of Smyrna.

[2] Ghéve is the commercial name for opium from Geiveh on the river Sakaria, running into the Black Sea. It appears to find its way to Constantinople *via* the port of Ismid, and hence is known also by the latter name.

[3] In 1882-83 India exported to China and other places a total of 91,798 chests (126,789 cwts.) of opium, valued at £11,481,376.

prepared for the poppy-culture. Under less favourable circumstances the land is prepared from July till October by ploughing, weeding, and manuring. The seed is sown between the 1st and 15th of November, and germinates in ten or fifteen days. The fields are divided for purposes of irrigation into beds about 10 feet square, which usually are irrigated twice between November and February, but if the season be cold, with hardly any rain, the operation is repeated five or six times. When the seedlings are 2 or 3 inches high they are thinned out and weeded. The plants during growth are liable to injury by severe frost, excessive rain, insects, fungi, and the growth of a root-parasite (*Orobanche indica*). The poppy blossoms about the middle of February, and the petals when about to fall are collected for the purpose of making "leaves" for the spherical coverings of the balls of opium. These are made by heating a circular-ridged earthen plate over a slow fire, and spreading the petals, a few at a time, over its surface. As the juice exudes, more petals are pressed on to them with a cloth until a layer of sufficient thickness is obtained. The leaves are forwarded to the opium-factories, where they are sorted into three classes, according to size and colour, the smaller and dark-coloured being reserved for the inside of the shells of the opium-balls, and the larger and least coloured for the outside. These are valued respectively at 10 to 7 and 5 rupees per maund of 82⅔ lb. The collection of

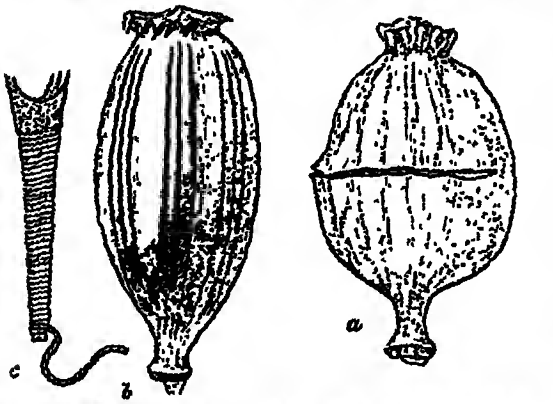

Fig. 2.—Opium Poppy Capsules, &c., ⅔ natural size. *a*, capsule showing mode of incision practised in Turkey; *b*, capsule as incised in India; *c*, nushtur, or instrument used in India for making the incisions. Drawn from specimens in the Museum of the Pharmaceutical Society of Great Britain.

opium commences in Behar about 25th February, and continues to about 25th March, but in Malwa is performed in March and April. The capsules are scarified vertically (fig. 2, *b*) in most districts (although in some the incisions are made horizontally, as in Asia Minor), the "nushtur" or cutting instrument being drawn twice upwards for each incision, and repeated two to six times at intervals of two or three days. The nushtur (fig. 2, *c*) consists of three to five flattened blades forked at the larger end, and separated about one-sixteenth of an inch from each other by winding cotton thread between them, the whole being also bound together by thread, and the protrusion of the points being restricted to one-twelfth of an inch, by which the depth of the incision is limited. The operation is usually performed about three or four o'clock in the afternoon, and the opium collected the next morning. In Bengal a small sheet-iron scoop or "seetoah" is used for scraping off the dried juice, and, as it becomes filled, the opium is emptied into an earthen pot carried for the purpose. In Malwa a flat scraper is employed, a small piece of cotton soaked in linseed oil being attached to the upper part of the blade, and used for smearing the thumb and edge of the scraper to prevent adhesion of the juice; sometimes water is used instead of oil, but both practices injure the quality of the product. Sometimes the opium is in a fluid state by reason of dew, and in some places it is rendered still more so by the practice adopted by collectors of washing their scrapers, and adding the washings to the morning's collection. The juice, when brought home, is consequently a wet granular mass of pinkish colour, from which a dark fluid drains to the bottom of the vessel. In order to get rid of this fluid, called "pasewa" or "pussewah," the opium is placed in a shallow earthen vessel tilted on one side, and the pussewah drained off. The residual mass is then exposed to the air in the shade, and regularly turned over every few days, until it has reached the proper consistence, which takes place in about three or four weeks. The drug is then taken to the Government fact[illegible]-time is conti-is turned out of the pots into wide [illegible] it is weigh[illegible] in [illegible] Chinese when Ind[illegible] to be sold. It is then examined conjunct[illegible]) as to impurities, colour, fracture,

[1] Mr R. Saunders of Ghaz. determine the amount of moisture, 652) that it was introduced [illegible]ent., a weighed sample is evaporated the Dutch, who purchased the [illegible] surface heated by steam. Adul-India Company held possessions [illegible]dered charcoal, soot, cow-dung,

powdered poppy petals, and powdered seeds of various kinds are easily detected by breaking up the drug in cold water. Flour, potato-flour, ghee, and ghoor (crude date-sugar) are revealed by their odour and the consistence they impart. Various other adulterants are sometimes used, such as the inspissated juice of the prickly pear, extracts from tobacco, stramonium, and hemp, pulp of the tamarind and bael fruit, mahwah flowers, and gums of different kinds. The price paid to the cultivator is regulated chiefly by the amount of water contained in the drug. When received into the Government stores the opium is kept in large wooden boxes holding about 50 maunds and occasionally stirred up, if only a little below the standard. If containing much water it is placed in shallow wooden drawers and constantly turned over. During the process it deepens in colour. From the store about 250 maunds are taken daily to be manufactured into cakes.

Various portions, each weighing 10 sers (of $2\frac{1}{16}$ lb), are selected by test assay so as to ensure the mass being of standard consistence (70 per cent. of the pure dry drug and 30 per cent. of water), and are thrown into shallow drawers and kneaded together. The mass is then packed into boxes all of one size, and a specimen of each again assayed, the mean of the whole being taken as the average. Before evening these boxes are emptied into wooden vats 20 feet long, 3½ feet wide, and 1½ feet deep, and the opium further kneaded and mixed by men wading through it from end to end until it appears to be of a uniform consistence. Next morning the manufacture of the opium into balls commences. The workman sits on a wooden stand, with a brass cup before him, which he lines with the leaves of poppy petals before-mentioned until the thickness of half an inch is reached, a few being allowed to hang over the cup; the leaves are agglutinated by means of "lewa," a pasty fluid which consists of a mixture of inferior opium, 8 per cent. of pasewa, and the "dhoo" or washings of the vessels that have contained opium, and the whole is made of such consistence that 100 grains evaporated to dryness over a water-bath leave 53 grains of solid residue. All the ingredients for the opium-ball are furnished to the workmen by measure. When the inside of the brass cup is ready a ball of opium previously weighed is placed on the leafy case in it, and the upper half of it covered with leaves in the same way that the casing for the lower half was made, the overhanging leaves of the lower half being pressed upwards and the sphere completed by one large leaf which is placed over the upper half. The ball, which resembles a Dutch cheese in size and shape, is now rolled in "poppy trash" made from the coarsely-powdered leaves, capsules, and stalks of the poppy plant, and is placed in an earthen cup of the same size as the brass one; the cups are then placed in dishes and the opium exposed to the sun to dry for three days, being constantly turned and examined. If it becomes distended the ball is pierced to liberate the gas and again lightly closed. On the third evening the cups are placed in open frames which allow free circulation of the air. This operation is usually completed by the end of July. The balls thus made consist on the average of—

Standard opium	1	ser	7·50	chittacks.
Lewa	0	„	3·75	„
Leaves (poppy petals)	0	„	5·43	„
Poppy trash	0	„	0·50	„
	2	sers	1·18	chittacks.

The average number of cakes that can be made daily by one man is about 70, although 90 to 100 are sometimes turned out by clever workmen. The cakes are liable to become mildewed, and require constant turning and occasional rubbing in dry "poppy trash" to remove the mildew, and strengthening in weak places with fresh poppy leaves. By October the cakes are dry and fairly solid, and are then packed in chests, which are divided into two tiers of twenty square compartments for the reception of as many cakes, which are steadied by a packing of loose poppy trash.[1] Each case contains about 120 catties (about 160 lb). The chests need to be kept in a dry warehouse for a length of time, but ultimately the opium ceases to lose moisture to the shell, and the latter becomes extremely solid. This is known as "provision" opium.

For home consumption Bengal opium is prepared in a different shape, and is known as Abkari or excisable opium. It is exposed to the heat of the sun until it contains only 10 per cent. of moisture, and is then formed into square cakes of 2 lb each, which are wrapped in oiled paper, or it is made into flat square tablets. In this form it has not the aroma of the ball-opium.

The care bestowed on the selection and preparation of the drug in the Bengal opium-factories i[illegible] such that the merchants who purchase it rarely [illegible] subsequently to examine it, although permission is given to open at each sale any number of chests or cakes that they may desire.

In Malwa the opium is manufactured by private enterprise, the Government levying an export duty of 600 rupees (£60) per chest. It is not made into balls but into rectangular or rounded masses, and is not cased in poppy petals. It contains as much as 95 per cent. of dry opium, but is of much less uniform quality than the Bengal drug, and, having no guarantee as to purity, is not con-

[1] This is purchased from the ryots at 12 annas per maund.

sidered so valuable. The cultivation in Malwa does not differ in any important particular from that in Bengal. The opium is collected in March and April, and the crude drug or "chick" is thrown into an earthen vessel and covered with linseed oil to prevent evaporation. In this state it is sold to itinerant dealers. It is afterwards tied up in quantities of 25 ℔ and 50 ℔ in double bags of sheeting, which are suspended to a ceiling out of the light and draught to allow the excess of oil to drain off. This takes place in seven to ten days, but the bags are left for four to six weeks until the oil remaining on the opium has become oxidized and hardened. In June and July, when the rains begin, the bags are taken down and emptied into shallow vats 10 to 15 feet across, and 6 to 8 inches deep, in which the opium is kneaded until uniform in colour and consistence and tough enough to be formed into cakes of 8 or 10 ounces in weight. These are thrown into a basket containing chaff made from the capsules. They are then rolled in broken leaves and stalks of the poppy and left, with occasional turning, for a week or so, when they become hard enough to bear packing. In October and November they are weighed and sent to market, packed in chests containing as nearly as possible 1 picul = 133⅓ ℔, the petals and leaves of the poppy being used as packing materials. The production is said to amount to abont 20,000 chests annually.

The amount of opium revenue collected in India was £10,480,051 in 1881. It is a remarkable fact that the only Indian opium ever seen in England is an occasional sample of the Malwa sort, whilst the Government monopoly opium is quite unknown; indeed, the whole of the opium used in medicine in Europe and the United States is obtained from Turkey. This is in some measure due to the fact that Indian opium contains less morphia. It has recently been shown, however, that opium grown in the hilly districts of the Himalayas yields 50 per cent. more morphia than that of the plains, and that the deficiency of morphia in the Indian drug is due, in some measure, to the long exposure to the air in a semi-liquid state which it undergoes. In view, therefore, of the probable decline in the Chinese demand, the cultivation of the drug for the European market in the hilly districts of India, and its preparation after the mode adopted in Turkey, viz., by drying the concrete juice as quickly as possible, might be worthy of the consideration of the British Government.

Persia.—The variety of poppy grown in Persia appears to be *P. somniferum*, var. *γ. album* (*P. officinale*, Gm.), having roundish ovate capsules. It is most largely produced in the districts of Ispahan, Shiraz, Yezd, and Khonsar, and to a less extent in those of Khorasan, Kermanshah, and Fars. The Yezd opium is considered better than that of Ispahan, but the strongest or *Theriak-e-Arabistani* is produced in the neighbourhood of Dizful and Shuster, east of the river Tigris. Good opium is also produced about Sari and Balfarush in the province of Mazanderan. The capsules are incised vertically, or in some districts vertical cuts with diagonal branches are made. The crop is collected in May and June and reaches the ports for exportation between September and January. Although the cultivation of opium in Persia was probably carried on at an earlier date than in India, Persian opium was almost unknown in England until about the year 1870, except in the form of the inferior quality known as "Trebizond," which usually contains only 0·2 to 3 per cent. of morphia. This opium is in the form of cylindrical sticks about 6 inches long and half an inch in diameter, wrapped in waxed paper. Since 1870 Persian opium has been largely exported from Bushire and Bandar-Abbas in the Persian Gulf to London, the Straits Settlements, and China. At that date the annual yield is said not to have exceeded 2600 cases; but, the profits on opium having about that time attracted attention, all available ground was utilized for this to the exclusion of cereals, cotton, and other produce. The result was a severe famine in 1871-72, which was further aggravated by drought and other cir- cumstances. Notwithstanding the lesson thus taught, the cultiva- tion is being extended every year, especially in Ispahan, which abounds in streams and rivers, an advantage in which Yezd is defi- cient. About Shiraz, Behbehan, and Kermanshah it now occupies much of the land, and has consequently affected the price and growth of cereals. The trade—only 300 chests in 1859—gradually increased until 1877, when the Persian opium was much adulter- ated with glucose. The heavy losses on this inferior opium and the higher prices obtained for the genuine article led to a great improve- ment in its preparation, and in 1880 the export had increased to 7700 chests. Abont five-sixths of this total finds its way to the Chinese market, chiefly by sea, although some is carried overland through Bokhara, Khokand, and Kashgar; a considerable quantity is exported by way of Trebizond and Samsun to Constantinople, and the remainder to Great Britain. The produce of Ispahan and Fars is carried for exportation to Bushire, and that of Khorasan and Kirman and Yezd partly to Bushire and partly to Bandar-Abbas. The Shuster opium is sent partly *via* Bushire to Muscat for transhipment to Zanzibar, and part is believed to be smuggled into India by way of Baluchistan and Mekran. Smaller quantities grown in Teheran, Tabriz, and Kermanshah find their way to Smyrna, where it is mixed with the local drug for the European market, the same practice being carried on at Constantinople with the Persian opium that arrives there from Samsun and Trebizond. For the Chinese market the opium is usually packed in chests containing 10½ shahmans (of 13½ ℔), so that on arrival it may weigh 1 Chinese picul (= 133⅓ ℔), 5 to 10 per cent. being allowed for loss by drying. At Ispahan, Shiraz, and Yezd the drug, after being dried in the sun, is mixed with oil in the proportion of 6 or 7 ℔ to 141 ℔ of opium, with the object, it is said, of suiting the taste of the Chinese,—that intended for the London market being usually free from oil.

Persian opinm, as met with in the London market, occurs in several forms, the most common being that of broad rounded cones weighing 6 to 10 oz. or more, or rarely twice that size. These are packed in poppy trash, or are wrapped separately in paper, or sometimes in poppy, fig, or vine leaves. Ispahan opium also occurs in the form of parallelepipeds weighing abont 16 to 20 oz.; sometimes flat circular pieces weighing about 20 oz. are met with. The opium is usually of mnch firmer and smoother consistence than that of Turkey, of a chocolate-brown colour and cheesy appearance, the pieces bearing evidence of having been beaten into a uniform mass previously to being made into lumps. The odour differs but slightly, except in oily specimens, from that of Turkey opium. Great care is now taken to prevent adulteration, and consequently Persian opium can be obtained nearly as rich in morphia as the Turkish drug,—on the average from 8 to 12 per cent. The greater proportion of the Persian opium imported into London is again exported, a comparatively small quantity being used, chiefly for the manufacture of morphia when Turkey opium is dear, and a little in veterinary practice. According to Dr Reveil, Persian opium usually contains 75 to 84 per cent. of matter soluble in water, and some samples contain from 13 to 30 per cent. of glucose.

China.—The variety of poppy grown in China appears to be chiefly the *P. somniferum*, *γ. album*, especially in the low lands, bnt red and purple varieties are also met with. The production is principally carried on in the south-western provinces of Szechuen, Yunnan, and Kweichow. It is grown to a less extent in Shanse, Shense, and Shantung in the north, as well as in eastern Mongolia and north-eastern Manchuria and Shingking; but in these provinces the richest soil and the ntmost care are necessary to ensure the success of the crop, and the area under opium cannot be greatly extended. Formerly the province of Shense produced 30 per cent. of the native product, bnt since the famine caused by the neglect of cereals for opium the extension of the cultivation has been rigidly prohibited in Shense, Honan, and Chihli. In Kwangtung the soil and climate have been found unsuitable, and in Fuhkeen sugar proves equally remunerative, if not more so. There can be no question, however, that, as already stated, the cultivation of the poppy is extending rapidly, in spite of prohibitory edicts issued from time to time; four-fifths of the opium at present used in China is home-grown. According to Consul Spence's report (1882) the poppy is cultivated chiefly on land near villages where manure and labour can be easily obtained. As soon as the summer crop has been reaped the land is ploughed and cleaned, roots and weeds are burnt and the resulting ashes scattered over the ground, and dressings of night-soil are liberally applied. The seeds are sown in November and December in drills 18 inches apart. In January, when the plants are a few inches high, the rows are thinned and earthed up so as to leave a free passage between. The ground is afterwards weeded occasionally and the earth stirred up. The poppy blooms in March or April, according to the situation. As soon as the capsules begin to form, dressings of liquid manure are given, and in April and May the opinm is collected. Vertical in- cisions are made in the capsules as in India. In some districts, however, a vertical shaving appears to be taken off the surface of the capsule. The excreted juice is scraped off and transferred to a small pot suspended at the waist. The mode of preparation for the market has not been described, but, from the occasional samples that have been sent to England, the opinm appears to have undergone manipulation, since it has a uniform pasty consistence and is with- out any trace of the grannlar structure indicative of unmixed opium like that of Turkey. The colour is darker and the consistence softer than that of Persian opinm, but the odour is good. Some of the Szechuen opium appears to have been mixed with oil. The Yunnan and Szechuen opiums are made into flat cakes, and are wrapped in white paper. Chekeang opium is in the form of treacly extract, and is sold in jars containing 2 to 4 ℔. The yield of opium is calculated at 350 oz. per acre. The Sheuse drug is highly esteemed because it has a flavour resembling the Patna kind and gives 85 to 90 per cent. of extract. Yunnan opium comes next and Szechuen third in value.

[illegible] by the Chinese bears some relation to The use of foreign opium [illegible] [illegible]der:—Patna, Malwa, its introduction, which was in the following [illegible] preferred along Benares, and Persian. Thus the Patna opium is [illegible] except the south-eastern coast as far north as the Yangtsze river, [illegible] in the district about Ningpo. Malwa is chiefly consumed in the northern provinces, including part of Kwangtung, Kwangse, Keangse, and Ganhwuy, while Benares is the favourite kind in

Formosa and some parts of Fuhkeen. Persian replaces the Malwa to a limited extent on account of its lower price; it goes principally to the province of Kwangse. Malwa opium is reputed to have a strong flavour and biting taste, and to be more stimulating; it is said to cause heartburn in those unaccustomed to its use, to induce an unhealthy action of the skin, and to prove irritating to the nervous system. Patna is considered mild but narcotic. Persian is also reckoned hot and acrid, and apt to cause dysentery. In some respects the native opium is comparable to the Malwa, having a coarser and more fiery flavour than the Patna, and also has the disadvantage of causing troublesome eruptions on the skin. It is said to be frequently adulterated with seaweed, jelly, oil, &c. It seems worthy of inquiry how far this difference of flavour and action may be due to the oil with which both Malwa and Chinese opiums are often prepared. The native opium is said to have the advantage over the foreign that the habit of smoking it can be broken off with comparative ease, which is not the case with the Indian drug.

Egypt.—The variety grown in Egypt is the same as in Asia Minor. The cultivation is carried on in Upper Egypt near Esneh, Kenneh, and Siout. The capsules are incised in March by drawing a knife twice round them horizontally. The concreted juice is scraped off next day by a scoop-knife, collected on a leaf, and placed in the shade to harden. Good samples, which are of rare occurrence, yield 9 to 12 per cent. of morphia; but, as a rule, the plant is grown in too moist a soil, scarification is not always performed at the right date, and adulteration is extensively practised, so that the average yield of morphia is only 3 to 4 per cent. As met with in English commerce Egyptian opium is in the form of hard, flat, circular cakes about 4 inches in diameter, covered with poppy and other leaves, but free from the *Rumex* fruits usually seen on Turkey opium. The fracture is porous, dark liver-coloured, with shining embedded particles and reddish yellow points, and occasionally starchy granules. The total amount exported in 1879 was valued at £2310, of which there was sent to Italy £990, France £630, Greece £540, and Turkey £150. It is not now regularly imported into Britain owing to its inferior quality. M. Gastinel found that, when cultivated in his garden at Cairo, the poppies yielded 10 to 12 per cent. of morphia when the capsules were nearly ripe, while opium collected immediately after the flowering was over contained only 3 to 4 per cent.

Algeria.—Opium has been grown in Algeria, but this kind is not known in English commerce.

Mozambique.—A company was established in Lisbon in 1877, with a grant of 50,000 acres of land in Mozambique, and certain exclusive privileges; the cultivation was commenced in 1879 and was carried on at Chaima between the Mulo and Quaqua rivers. The ground has been sown with Malwa seed, the plants thrive well, and the capsules are larger than those grown in India. The collection of opium is made about seventy-five days after the seed has been sown, and the yield compares favourably with that obtained in India. It is said to be mixed on the spot with 80 to 100 per cent. of a special matter known only to the cultivators. The mixture is made into balls weighing about 1 lb; these are packed in boxes with poppy trash and covered with a layer of indigenous cotton. The yield from the first crop amounted only to a few pounds, and upon examination proved to be of moderate quality only. It was of soft consistence, brownish colour, and yielded 4 per cent. of morphia and 4·3 per cent. of narcotin, and 40·9 per cent. of moisture. In 1884 specimens were sent to the London market in the form of spherical balls, having the size and general appearance of Malwa and evidently intended to compete with it in the Chinese market.

Australia.—Experiments in opium-cultivation have been made during the last ten years in the neighbourhood of Melbourne, near Bairnsdale in Gippsland, and at Dromana on Port Phillip Bay, and a few cwts. of opium have been obtained. The first specimens collected contained only 2 per cent. of morphia and about 8 per cent. of narcotin; in subsequent experiments opium yielding 4 to 10 per cent. of morphia was obtained. The seed, procured from Smyrna, was sown in June, July, and the beginning of August, and the opium collected in the summer months of January, February, and March. The plants attained a height of 5 to 7 feet, and each produced three or four large white flowers. The East India variety, with double purple or nearly black flowers, was found to produce only one flower and give but little opium. It seems probable that, with greater care in selection of sheltered hilly localities and rich soil for the cultivation of the poppy, and attention to the very important point of collecting the juice at exactly the right time, opium of very excellent quality might be produced in Australia in sufficient quantity to meet the local demand.

Europe.—Experiments made in England, France, Italy, Swit[illegible] land, Greece, Spain, Germany, and [illegible] to be sold. It [illegible] opium as rich in morph[illegible] by the [illegible] vessels [illegible] Switzer- duced in Europ[illegible] succeeded [illegible] China, No[illegible] in Sweden prove that conju[illegible] as that of Eastern countries can be pro-

¹ Mr [illegible]. In 1830 Mr Young, a surgeon at Edinburgh, [illegible] in obtaining 56 lb of opium from an acre of poppies, and sold it at 36s. per lb. In France the cultivation has been carried on since 1844 at Clermont-Ferrand by M. Aubergier. The juice, of which a workman is able to collect about 9·64 troy oz. in a day, is evaporated by artificial heat immediately after collection. The juice yields about one-fourth of its weight of opium, and the percentage of morphia varies according to the variety of poppy used, the purple one giving the best results. By mixing assayed samples he is able to produce an opium containing uniformly 10 per cent. of morphia. It is made up in cakes of 50 grammes, but is not produced in sufficient quantity to become an article of wholesale commerce. Some specimens of French opium have been found by Guibourt to yield 22·8 per cent. of morphia, being the highest percentage observed as yet in any opium. Experiments made in Germany by Karsten, Jobst, and Vulpius have shown that it is possible to obtain in that country opium of excellent quality, containing from 8 to 13 per cent. of morphia. It was found that the method yielding the best results was to make incisions in the poppy-heads soon after sunrise, to collect the juice with the finger immediately after incision, and evaporate it as speedily as possible, the colour of the opium being lighter and the percentage of morphia greater than when the juice was allowed to dry on the plant. Cutting through the poppy-head caused the shrivelling up of the young fruit, but the heads which had been carefully incised yielded more seed than those which had not been cut at all. Newly-manured soil was found to act prejudicially on the poppy. The giant variety of poppy yielded most morphia.

The difficulty of obtaining the requisite amount of cheap labour at the exact time it is needed and the uncertainty of the weather render the cultivation of opium too much a matter of speculation for it ever to become a regular crop in most European countries.

North America.—In 1865 the cultivation of opium was attempted in Virginia by Mr A. Robertson, and a product was obtained which yielded 4 per cent. of morphia. In 1867 Dr H. Black grew opium in Tennessee which contained 10 per cent. of morphia. Opium produced in California by Dr H. Flint in 1873 yielded 7½ per cent. of morphia, equal to 10 per cent. in perfectly-dried opium. The expense of cultivation exceeded the returns obtained by its sale. As in Europe, therefore, the high price of labour militates against its production on a large scale.

Chemical Constitution.—The activity of opium is principally due to the vegetable alkaloid morphia or morphine, which opium of good quality contains to the extent of 8 to 17 per cent., the average amount being 10 per cent. Opium yielding less than this is considered of inferior grade and below the commercial standard for use in medicine.

Morphia is interesting as being the first one that was discovered of the now large class of bodies known as alkaloids. Its basic nature was first clearly pointed out in 1816 by Sertürner. It exists in opium in combination with sulphuric and meconic acids. Lactic acid has also been found in opium, but is believed to be formed in it subsequently to the collection of the drug.

Besides morphia several other basic substances have been detected in different varieties of opium, but only in minute quantities, rarely amounting to 1 per cent. These are narceia; codeia, 0·2 to 0·4 per cent.; thebaia, 0·15 to 1·0 per cent.; papaveria, 1·0 per cent.; cryptopia, meconidia, hydrocotarnia, laudanosia, protopia, codamia, gnoscopia; also a few other bodies of a feebly alkaline or neutral character, viz., narcotin, 2 to 8 per cent.; pseudomorphin, 0·02; lanthopin, ·005; and meconoiosin.

Opium also contains in considerable quantity a resinoid body which is soluble in its own weight of water, but is thrown down when this solution is diluted with ten times its bulk of water; 11 per cent. of caoutchouc; a gum distinct from gum arabic; pectin; albumen; wax, consisting of palmitate and cerotate of cerotyl; and 4 to 8 per cent. of calcareous salts. Sugar has been frequently found in opium, but whether natural or added as an adulteration is not known. The amount of caoutchouc present has probably some bearing on the value of opium for smoking, since the Chinese estimate its value roughly by the "touch," *i.e.*, the rapidity or slowness with which a thread drawn out from the [illegible] the mass will break by its own weight.

Of the alkaloids above mentioned only three are used to any extent in medicine, viz., morphia, codeia, and narcotin. Narceia has also been used in medicine in France.

Morphia, $C_{17}H_{19}NO_3$.—Turkey opium of good quality and freed from moisture contains from 10 to 15 per cent. of morphia, and if less than 10 per cent. be present it is probably more or less adulterated. Persian opium is very variable in this respect, when of good

quality yielding from 8 to 13 per cent., while the variety met with in the form of sticks sometimes contains only 0·2 to 3 per cent. Indian opium is remarkable for the low percentage of morphia, the average yield being only 3 to 4 per cent., although samples of the kinds known as Khandesh and Garden Patna have afforded on analysis 6 to 7 per cent. Chinese opium is similar in this respect, giving, as a rule, only 3 to 7 per cent. of this alkaloid. The amount of morphia present in opium bears no relation to the preference exhibited by smokers, opium containing a large quantity of morphia being generally considered by them as inferior in quality and apt to cause headache. For use in medicine those containing a large percentage of morphia are the most esteemed. Opium dried as soon as possible after being collected is usually much richer in morphia than that kept for some time in a moist state and exposed to the air; and poppies grown on the hills yield an opium containing more morphia than those cultivated on the plains. Guibourt found that opium twenty years old contained less morphia than when previously analysed in the fresh state. To ascertain the percentage of morphia, the merchant extracts, by means of an instrument like a cheese-cutter, a small cylinder of opinm about the thickness of a penholder and about 2 inches long, out of one-third of the pieces in a chest, and it is considered that the analysis of these pieces will fairly represent the value of the chest. Various methods are adopted for estimating the morphia, most of which depend upon the fact that this alkaloid can be precipitated from its salts by ammonia, and that it is insoluble in ether and only very slightly soluble in cold water. When pure it forms colourless shining prismatic crystals having an alkaline reaction. It unites with acids to form salts, most of which are soluble in water. It is soluble in 36 parts of boiling and 100 of cold alcohol, in 500 of boiling water, and very slightly in chloroform. It is also soluble in the fixed and volatile oils, and in solution of the fixed caustic alkalis and lime water, but only very slightly in caustic ammonia. With nitric acid it gives a red colour passing into yellow, with test solution of ferric chloride a blue colour which is destroyed by free acids or alcohol, and with sulphuric acid and bichromate of potash a greenish but not a purple or violet colour. Heated in the open air it burns readily, a portion being volatilized. The salts chiefly used in medicine are the hydrochlorate, sulphate, and acetate; and for subcutaneous injection the tartrate has been recommended by Erskine Stuart, since it is more soluble, and more concentrated solutions can be used of it than of the other salts. Heated in a sealed tube with hydrochloric acid, morphia is decomposed and an alkaloid named "apomorphia," $C_{17}H_{17}NO_2$, formed, which is one of the most speedy and effectual emetics known, and is of great value in cases of accidental poisoning, the subcutaneous injection causing the emptying of the contents of the stomach in a few minutes even when all ordinary emetics fail to act. In minute doses it has also valuable expectorant properties. It is soluble in ether and 50 parts of alcohol and in 68 parts of boiling water, but the solution soon decomposes, and assumes a green colour; consequently it should be made fresh for use in medicine.

Codeia, $C_{18}H_{21}NO_3$, exists in opium in combination with meconic acid, and remains in solution after the morphia is precipitated by ammonia; it may be obtained by evaporating the solution and purifying the crystals that form by dissolving them in hot ether, from which it crystallizes out on cooling in rather large octahedral prisms. It differs from morphia in not being soluble in solution of caustic potash or soda, while with nitric acid (sp. gr. 1·200) it gives a yellow solution which does not become red. It is soluble in 17 parts of boiling and 80 of cold water. Codeia has been found also in Turkish, French, and Indian opiums.

Narcotin, $C_{22}H_{23}NO_7$.—This substance exists chiefly in a free state in opium; being insoluble in cold water, it is left behind in considerable quantity when opium is macerated in that liquid, although a small portion, probably in combination with sulphuric acid, is dissolved. It is, however, very soluble in ether and benzol, and may be readily obtained by means of these solvents from the crude drug. It is doubtful if it should be classed with the alkaloids, for, although it forms definite compounds with some of the mineral acids, it does not exert any influence on vegetable colours. It differs from morphia in being insoluble in the caustic alkalis and not producing a blue colour with ferric salts. When heated on a piece of paper over a candle it leaves a greasy stain.

Narceia, $C_{23}H_{29}NO_9$, has been also used occasionally in medicine. Its alkaloidal character has been disputed; but it is now generally classed as an alkaloid. It differs from morphia in giving a blue colour with dilute mineral acids, but does not give a blue colour with ferric salts or a red colour with nitric acid. For recent details concerning the less important alkaloids reference may be made to Dr Hesse's papers, translated in the *Pharm. Journ. and Trans.*, September 1870, p. 205, and January 1872, p. 549.

Opium of good quality for medicinal use should not lose more than 12½ per cent. of water in drying, should not yield more than 8 per cent. of ash from the dried drug, and ought to afford at least 60 per cent. of matter soluble in water. It should be of somewhat tenacious consistence, yellowish brown colour, strong narcotic odour, and bitter taste. The preparation of crude opium most largely used in medicine is the tincture, commonly known as "laudanum." It is composed of 1½ oz. of powdered opium and 1 pint of spirit of wine of specific gravity 0·920. This name was, however, at first applied to a solid preparation, a pill-mass made of opium and various aromatics, which in the *London Pharmacopœia* of 1639 consisted of saffron, castor, ambergris, musk, and oil of nutmeg. The liquid preparation which bears the name of laudanum was apparently first introduced by the celebrated Dr Sydenham, and was inserted in the *London Pharmacopœia* for 1721. It also contained aromatics.

Physiological Action.—See NARCOTICS, *supra*, pp. 231-2.

Medicinal Uses.—The chief value of opium is to relieve pain, to relax spasm, to allay both local and general irritation of the nervous system, and to procure sleep. Its power of diminishing secretions is taken advantage of in the cure of catarrh, bronchorrhœa, diarrhœa, and other forms of inflammation of the mucous membranes accompanied with excessive secretion, and also in diabetes. It is found of great value when conjoined with emetics in improving or stimulating the secretions of the skin. Its use is dangerous in inflammation of the brain or determination of blood to the head. The action of opium is exerted much more powerfully in proportion upon infants than upon adults, as small a dose as one drop of laudanum having proved fatal to an infant. For remedies in cases of poisoning see POISONS. Morphia differs slightly in its properties from opium. It is less stimulant, and does not produce the full diaphoretic action; it causes less headache, nausea, and constipation. When used hypodermically its action is more rapid and smaller doses are required. Codeia is used in diabetes, in coughs, &c. Narceia is considered to be purely hypnotic. Narcotin is official in the pharmacopœia of India as a tonic in general debility arising from prolonged lactation, and in convalescence from acute febrile and inflammatory diseases.

Opium-eating.—Opium, like many other poisons, produces after a time a less effect if frequently administered as a medicine, so that the dose has to be constantly increased to produce the same result on those who take it habitually. When it is used to relieve pain or diarrhœa, if the dose be not taken at the usual time the symptoms of the disease recur with such violence that the remedy is speedily resorted to as the only means of relief, and thus the habit is exceedingly difficult to break off. Opium-eating is chiefly practised in Asia Minor, Persia, and India. Opinions differ widely as to the injurious effect of the habit; the weight of evidence appears, however, to indicate that it is much more deleterious than opium-smoking. It has been practised in India from very ancient times; some idea of its prevalence there may be gathered from the fact that the mere licence fees for one year amounted to £493,343, and that some of the opium dealers in Calcutta have each no less than seventeen shops where this drug only is sold.

The following statistics collected by Vincent Richards regarding Balasor in Orissa throw some light on the influence of this practice on the health. He estimates that one in every 12 or 14 of the population use the drug, and that the habit is increasing. Of the 613 opium-eaters examined by him he found that the average age at which the habit was commenced was 20 to 26 years for men and 24 to 30 years for women. Of this number 143 had taken the drug for from 10 to 20 years, 62 for from 20 to 30 years, and 38 for more than 30 years. The majority took their opium twice daily, morning and evening, the quantity taken varying from 2 to 46 grains daily, large doses being the exception, and the average 5 to 7 grains daily. The dose, when large, had been increased from the beginning; when small, there had usually been no increase at all. The causes which first led to the increase of the drug were disease, example, and a belief in its aphrodisiac powers. The diseases for which it was chiefly taken were malarial fever, dysentery, diarrhœa, spitting of blood, rheumatism, and elephantiasis. A number began to take it in the famine year, 1866, as if enabled them to exist on less food and mitigated their sufferings; others used it to enable them to undergo fatigue and to make long journeys. Mr Richards concludes that the excessive use of opium by the agricultural classes, who are the chief consumers in Orissa, is very rare indeed. Its moderate use may be and is indulged in for years without producing any decided or appreciable ill effect except weakening the reproductive powers,

the average number of the children of opium-eaters being 1·11 after 11 years of married life. It compares favourably as regards crime and insanity with intoxicating drinks, the inhabitants of Balasor being a particularly law-abiding race, and the insane forming only 0·0069 per cent. of the population. Dr W. Dymock of Bombay, speaking of western India, concurs in Mr Richards's opinion regarding the moderate use of the drug. He believes that excessive indulgence in it is confined to a comparatively small number of the wealthier classes of the community. Dr Moore's experience of Rajputana strongly supports the same views. It seems probable that violent physical exercise may counteract in great measure the deleterious effect of opium and prevent it from retarding the respiration, and that in such cases the beneficial effects are obtained without the noxious results which would accrue from its use to those engaged in sedentary pursuits. There is no doubt that the spread of the practice is connected with the ban imposed in Mohammedan countries on the use of alcoholic beverages, and to some extent with the long religious fasts of the Buddhists, Hindus, and Moslems, in which opium is used to allay hunger.

To break off the habit of opium-eating is exceedingly difficult, and can be effected only by actual external restraint, or the strongest effort of a powerful will, especially if the dose has been gradually increased. Various remedies have been proposed to support the system while the habit is being dropped, the most recent of which are coca and strychnia.

The habit is not confined to India, Persia, and Turkey, but is unfortunately practised in other forms in Western countries. In a few districts of England more opium is consumed than in the rest of the United Kingdom, and in the United States it is calculated that the number of opium-eaters is 82,696, and the average amount of opium consumed by each opium-eater in the State of Michigan is estimated at 1 oz. avoirdupois per week. Advanced opium-eaters also use in addition chloral and chloroform or ether. Of late years also the practice of using hypodermic injections of morphia has been followed as a luxury by many who have first experienced the speedy relief from pain obtained by its use.

Opium-smoking.—This is chiefly practised by the inhabitants of China and the islands of the Indian Archipelago, and in the countries where Chinese labour is largely employed. It is said to have commenced in China forty or fifty years before the English began to import opium into that country. In 1858 it was estimated that about 2,000,000 of Chinese smoked opium, and in 1878 from one-fourth to three-tenths of the entire population of 400,000,000.

For smoking the Chinese use an extract of opium, the privilege of preparing and the exclusive right to deal in which is let to the highest bidder by the Government for a fixed term of years. The present holder of the monopoly in Hong-Kong pays 205,000 dollars annually. The same arrangement is in vogue in Singapore, French Cochin China, and Macao. The process of preparation is thus described by Mr Hugh M'Callum, Government analyst at Hong-Kong:—

"The opium is removed from its covering of leaves, &c., moistened with a little water, and allowed to stand for about fourteen hours; it is then divided into pans, 2½ balls of opium and about 10 pints of water going to each pan; it is now boiled and stirred occasionally until a uniform mixture having the consistence of a thin paste is obtained. This operation takes from five to six hours. The paste is at once transferred to a larger pan and cold water added to about 3 gallons, covered, and allowed to stand for from fourteen to fifteen hours. A bunch of 'tang sain' (lamp-wick, the pith of some plant) is then inserted well into the mass, and the pan slightly canted, when a rich, clear, brown fluid is thus drawn off, and filtered through 'chi mui' (paper made from bamboo fibre). The residue is removed to a calico filter and thoroughly washed with boiling water, the wash water being reboiled and used time after time. The last washing is done with pure water; these washings are used in the next day's boiling.

"The residues on the calico filters are transferred to a large one of the same material and well pressed. This insoluble residue, called 'nai chai' (opium dirt), is the perquisite of the head boiling coolie, who finds a ready market for it in Canton, where it is used for adulterating, or rather in manufacturing, the moist inferior kinds of prepared opium. The filtrate or opium solution is concentrated by evaporation at the boiling point, with occasional stirring until of a proper consistence, the time required being from three to four hours; it is then removed from the fire and stirred with great vigour till cold, the cooling being accelerated by coolies with large fans. When quite cold it is taken to the hong and kept there for some months before it is considered in prime condition for smoking. As thus prepared it has the consistence of a thin treacly extract, and is called boiled or prepared opium. In this state it is largely exported from China to America, Australia, &c., being carefully sealed up in small pots having the name of the maker (i.e., hong) on each.

"The Chinese recognize the following grades of opium:—(1) 'raw opium,' as imported from India; (2) 'prepared opium,' opium made as above; (3) 'opium dross,' the scrapings from the opium pipe; this is reboiled and manufactured as a second-class prepared opium; a Chinese doctor stated lately at a coroner's inquest on a case of poisoning that it was more poisonous than the ordinary prepared opium; (4) 'nai chai' (opium dirt), the insoluble residue left on exhausting the raw opium thoroughly with water. The opium is sent every day from the hong (i.e., shop or firm) to the boiling-house, the previous day's boiling being then returned to the hong. The average quantity boiled each day is from six to eight chests of Patna opium, this being the only kind used."

By this process of preparation a considerable portion of the narcotin, caoutchouc, resin, oil, or fatty and insoluble matters are removed, and the prolonged boiling, evaporating, and baking over a naked fire tend to lessen the amount of alkaloids present in the extract. The only alkaloids likely to remain in the prepared opium, and capable of producing well-marked physiological results, are morphia, codeia, and narceia. Morphia, in the pure state, can be sublimed, but codeia and narceia are said not to give a sublimate. Even if sublimed in smoking opium, morphia would, in M'Callum's opinion, probably be deposited in the pipe before it reached the mouth of the smoker. The bitter taste of morphia is not noticeable when smoking opium, and it is therefore possible that the pleasure derived from smoking the drug is due to some product formed during combustion. This supposition is rendered probable by the fact that the opiums most prized by smokers are not those containing most morphia, and that the quality is judged by the amount of soluble matter in the opium, by its tenacity or "touch," and by peculiarities of aroma,—the Indian opium, especially the Patna kind, bearing much the same relation to the Chinese and Persian drug that champagne does to vin ordinaire. Opium-smoking is thus described by Mr Theo. Sampson of Canton:—

"The smoker, lying on his side, with his face towards the tray and his head resting on a high hard pillow (sometimes made of earthenware, but more frequently of bamboo covered with leather), takes the pipe in his hand; with the other hand he takes a dipper and puts the *sharp* end of it into the opium, which is of a treacly consistency. Twisting it round and round he gets a large drop of the fluid to adhere to the dipper; still twisting it round to prevent it falling he brings the drop over the flame of the lamp, and twirling it round and round he roasts it; all this is done with acquired dexterity. The opium must not be burnt or made too dry, but roasted gently till it looks like burnt worsted; every now and then he takes it away from the flame and rolls it (still on the end of the dipper) on the flat surface of the bowl. When it is roasted and rolled to his satisfaction he gently heats the centre of the bowl, where there is a small orifice; then he quickly thrusts the end of the dipper into the orifice, twirls it round smartly, and withdraws it; if this is properly done, the opium (now about the size of a grain of hemp-seed or a little larger) is left adhering to the bowl immediately over the orifice. It is now ready for smoking.

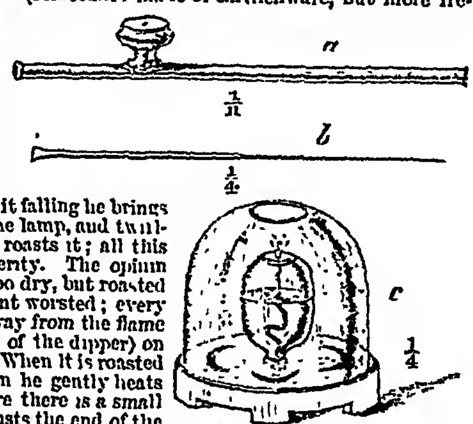

Fig. 3.—Opium-smoking Apparatus. *a*, pipe; *b*, dipper; *c*, lamp.

"The smoker assumes a comfortable attitude (lying down of course) at a proper distance from the lamp. He now puts the stem to his lips, and holds the bowl over the lamp. The heat causes the opium to frizzle, and the smoker takes three or four long inhalations, all the time using the dipper to bring every particle of the opium to the orifice as it burns away, but not taking his lips from the end of the stem, or the opium pellet from the lamp till all is finished. Then he uses the flattened end of the dipper to scrape away any little residue there may be left around the orifice, and proceeds to prepare another pipe. The preparations occupy from five to ten minutes, and the actual smoking about thirty seconds. The smoke is swallowed, and is exhaled through both the mouth and the nose."

Large quantities of morphia are exported to China from Europe for the purpose of preparing the so-called "cure for opium-smoking," which consists of one-third of a grain of hydrochlorate of morphia mixed with a little powdered rice. The powders are taken at gradually increasing intervals, until the morphia is left off altogether.

Mr. Allen Williams, in a work recently published, states that there are now nearly a million persons in the United States who indulge in opium-smoking, and the habit seems to be on the increase in New York and other eastern cities, as well as in the west. The records of the National Bureau of Statistics show that, while the number of the Chinese in the United States has remained nearly stationary since 1876, the amount of opium imported has increased from 189,354 ℔ of the crude and 49,375 ℔ of the prepared drug in 1872 to 243,211 ℔ of the former and 77,196 ℔ of the latter in 1880. Of the crude opium a certain quantity appears to be re-exported to the West Indies; the larger proportion of the prepared drug is used in San Francisco.

So far as can be gathered from the conflicting statements published on the subject, opium-smoking may be regarded much in the same light as the use of alcoholic stimulants. To the great majority of smokers who use it moderately it appears to act as a stimulant, and to enable them to undergo great fatigue and to go for a considerable time with little or no food. According to the reports given by authorities on the subject, when the smoker has plenty of active work it appears to be no more injurious than smoking tobacco. When carried to excess it becomes an inveterate habit; but this happens chiefly in individuals of weak will-power, who would just as easily become the victims of intoxicating drinks, and who are practically moral imbeciles, often addicted also to other forms of depravity. The effect in bad cases is to cause loss of appetite, a leaden pallor of the skin, and a degree of leanness so excessive as to make its victims appear like living skeletons. All inclination for exertion becomes gradually lost, business is neglected, and certain ruin to the smoker follows. There can be no doubt that the use of the drug is opposed by all thinking Chinese who are not pecuniarily interested in the opium trade or cultivation, for several reasons, among which may be mentioned the drain of bullion from the country, the decrease of population, the liability to famine through the cultivation of opium where cereals should be grown, and the corruption of state officials.

OPODELDOC, a name now applied to a liniment composed of soap, camphor, the volatile oils of rosemary and origanum, solution of ammonia, and spirit of wine. It is made of such a consistence that it is solid at ordinary temperatures, but melts with the warmth of the hand. The origin of the name is lost in obscurity, but is believed to have been first applied to a plaster, invented by Mindererus or Paracelsus, and used for bruises and external injuries. In the *Edinburgh Pharmacopœia* (1721) opodeldoc was official under the name of *unguentum opodeldoch*, and then consisted of thirteen aromatic ingredients besides Venice soap, camphor, and spirit of wine. Its first appearance in the *London Pharmacopœia* seems to have been in 1746 under the name of *linimentum saponaceum*. In the *British Pharmacopœia* of 1867 it is represented by the liniment of soap, which differs from the earlier preparations in being fluid at ordinary temperatures.

OPORTO (*i.e.*, *O Porto*, The Port), the second city of the kingdom of Portugal, the capital of Entre Douro e Minho, the best-cultivated and the most fruitful province of the country, is situated on both banks of the Douro, about 3 miles from its mouth, in 41° 9′ N. lat. and 8° 37′ W. long. The part south of the Douro is known as Villa Nova da Gaia. The mouth of the river is obstructed by a very dangerous shifting sandbank, protected by a lighthouse and a castle situated in the village of São João da Foz, which, along with Campanha, Paranhos, and Sordello, completes the suburbs. The population of the city is 80,295, and with the suburbs 108,346.

The view of the town from the river is singularly attractive and quaint. It possesses many buildings of interest, and picturesque thoroughfares, which, however,

Oporto and Mouth of the Douro.

from the situation of the city, are very steep and irregular. The principal edifices are the cathedral and the archbishop's palace—the latter, containing a fine staircase, conspicuously situated on a high rock—and the Torre dos Clerigos, a granite tower 210 feet high, built in 1748, commanding a splendid view, and visible at sea a long way off. The English factory (built in 1790), including a library, reading-room, and ballroom, is one of the largest buildings, while the exchange (once the monastery of S. Francisco) is perhaps the finest and most elaborately decorated structure in the country. The walls and floor of the hall are entirely covered with beautiful inlaid devices in polished native-coloured woods of all hues brought from the virgin forests of the Brazils. The museum, the public library, containing over 80,000 volumes, the barracks, the Da Miseracordia Hospital, and the opera-house are the other most important public buildings. The Rua Nova dos Inglezes is the most frequented street, and the Rua das Flores is one of the most interesting from the rich display of gold-work, for which the town is famous, both in its shop windows as well as—more characteristically and attractively—on the persons of the fishwomen in their everyday garb. The Praça de San Ovidio, situated on the heights, and laid out in terraces of flowers, deserves a visit from the traveller, while the Largo da Torre da Marva is interesting as standing on the site of the ancient Cale, from which the kingdom derives its name (Porto Cale). The chapel of Cedo Feita, said to have been founded in 559 by the Visigothic king Theodomir (but much more probably not till the 12th century), is very curious; the church of Nossa Senhora da Lapa, a well-known landmark, is a handsome Corinthian edifice. The city at one time had no less than 80 monasteries and chapels. The English community maintain a chaplain and a doctor, and have a cemetery for their own dead. Railways run from Oporto to Lisbon, and up the valley of the Douro to Pezo da Regoa, and recently a junction has been made with the line through Spain to Paris, whereby the long journey from Lisbon to that capital *via* Madrid is vastly shortened; a branch also runs to the frontier town of Valença on the Minho. Oporto possesses good schools, a medical college with numerous chairs, and a botanical garden. Several newspapers appear daily.

The industries of Oporto are the most important and numerous in the kingdom, employing about 6000 hands, the chief being paper, linen, wool, cotton, silk, and gold manufactures, brocade, lace, glove, button, and pottery making. Oporto is chiefly famous for the export of the wine which bears its name, of which the great storehouses are on the south side of the river. The vines from which it is made grow on the Alto Douro, a hilly and precipitous region lying about 60 miles up the river, and having an area of 27 miles in length by 5 or 6 in breadth, cut off from the sea, and shut in from the north-east by a range of mountains. The trade was established in 1678, but the shipments for some years did not exceed 600 pipes (of 115 gallons each). In 1703 Lord Methuen made a treaty with Portugal, under which Portuguese wines were admitted on easier terms than those of Gascony, and henceforward "port" began to be drunk. In 1747 the export reached 17,000 pipes. In 1754 the great wine monopoly company of Oporto originated, under which the shipments rose to 33,000 pipes. At the beginning of the present century the policy of the Government more and more favoured port wine, besides which the vintages from 1802 to 1815 were splendid both in Portugal and in Madeira,—that of 1815 has, in fact, never been excelled. For the next few years the grape crop was not at all good, but the 1820 vintage was the most remarkable of any. It was singularly sweet and black, besides being equal in quality to that of 1815. This henceforth became the standard taste and colour for true port, and to keep up the vintage of following years to this exceptional standard adulteration by elder-berries, syrup, and *jeropiga* was resorted to. This practice did not long continue, for it was cheaper to adulterate the best wines with inferior sorts of port wine itself. There is scarcely a Portuguese wine, says Crawfurd, in skilful and intelligent hands not capable of being made both sound and palatable without recourse to any sort of adulteration. Port is now one of the purest wines. In 1852 the *Oidium* which spread over Europe destroyed most of the Portuguese vineyards. In 1857 the second monopoly company was abolished, and since then the exports have been increasing till 1877, when the amount shipped was 61,278 pipes, of which England absorbed 38,598. Since 1863 the total exported has been 792,171 pipes (521,531 to England). In England port is adulterated with the red Spanish wine of Tarragona, which is a true wine, but procurable at half the cost of the cheapest port. The port wine duties are, however, not oppressive, and, though the *Phylloxera* has produced great ravages, the trade is still very prosperous. Brand wines are those made of different vintages blended together: "vintage" is a wine blended by nature herself, and is of rare occurrence.

Besides wine Oporto exports oranges (228,000,000 in 1878), onions, shipped as of Spanish growth, and varying vastly in amount according to the season, and olives (which go to Brazil alone, although they are cheaper and finer-flavoured when truly ripe than those of any other country). An important trade is done in live cattle. Portugal is one of the few countries never visited by the cattle-plague. They are sent to England as fat cattle, and are said to yield the finest grass-fed beef admitted into the country. About 15,000 head were imported in 1878. Feijões or haricot (mostly the black, feijão pret) beans form a considerable item of export to Brazil: 975,000 kilos were shipped in 1877. They are identical with those from Sorrento, and are a little dearer, but of a distinctly finer quality. Cork and sumach are also among the exports. The imports are numerous: codfish (bacalhão), a national dish, in immense quantities, as well as coals and ore, are brought from Newfoundland, and cottons and yarns from Great Britain (mostly), France, and Holland. Iron and steel goods were in 1877 imported from England to the amount of 7,000,000 kilos, paying a 5 per cent. *ad valorem* duty; in 1878, however, Sweden and Norway entered strongly into competition. Coal is also imported from England, and costs the consumer in Oporto twice its cost there. In 1878 of

215 steamers which entered Oporto (no vessel, owing to the dangerous bar, comes into this port to call simply) 153 were British.

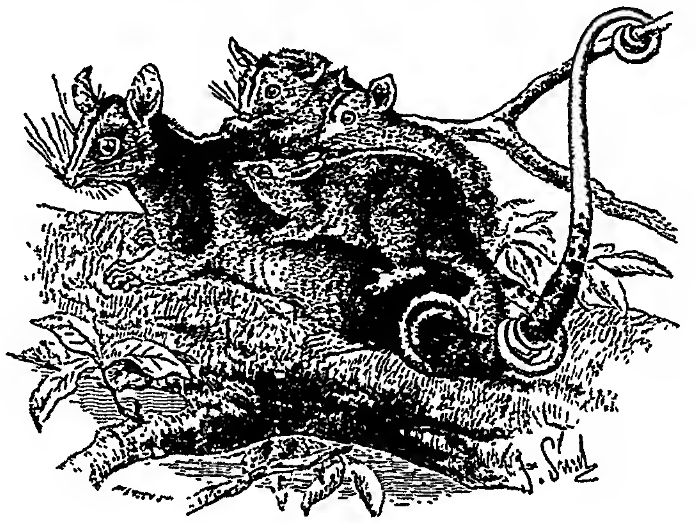
History.—The history of Oporto dates from an early period. Before the Roman invasion, under the name of Gaia, or Cago, it was a town with a good trade; the Alani subsequently founded a city on the opposite or northern bank, calling it *Castrum Novum*. About 540 A.D. the Goths under Leovogild obtained possession of the northern district, who yielded place in 716 to the Moors under Abdul Hassan, who then conquered the whole of that region. The Christians, however, again gained possession by the overthrow of the Moors, when it became the key of their position for the long period during which the latter held sway in the southern provinces of Portugal. The Moors once more became its masters for a short period, till in 1092 it was brought by Dom Alfonso Frederico finally under Christian domination. The town is renowned also in English military annals from the duke of Wellington's famous passage of the Douro in its immediate neighbourhood, close to where the fine bridge of the northern railway now spans the river, by which he surprised and put to flight Soult's army, capturing the city on the 11th May 1809. It sustained a severe siege in 1833 during the civil war headed by Dom Miguel, and was bravely defended by Dom Pedro with 7500 men, but with the loss of 16,000 of its inhabitants.

See *Commercial Reports* for 1878-79; *Report* of Wine Committee of House of Commons in 1879; Crawfurd, *Portugal, Old and New*, 1872. (H. O F.)

OPOSSUM. The animals to which this name is applied are the only non-Australian members of the Marsupials or pouched animals, being found throughout the greater part of the continent of America, from the United States to Patagonia, the number of species being largest in the more tropical parts (see MAMMALIA—*Marsupialia*, vol. xv. p. 380). They form the family *Didelphyidæ*, distinguished from the other Marsupial families by their equally developed hind-toes, their nailless but fully opposable hallux, and by their dentition, its formula being $i\frac{5}{4}\ c\frac{1}{1}\ pm\frac{3}{3}\ m\frac{4}{4}$, total 50, a number only exceeded among heterodont Mammalia by the Australian *Myrmecobius fasciatus*. The peculiarity in the mode of succession of these teeth has been explained in the article referred to, where also (p. 378) a figure of the teeth may be seen. Opossums are small animals, varying from the size of a mouse to that of a large cat, with long noses, ears, and tails, the latter being as a rule naked and prehensile, and with their great toes so fully opposable to the other digits as to constitute a functionally perfect posterior pair of "hands." These opposable great toes are without nail or claw, but their tips are expanded into broad flat pads, which are no doubt of the greatest use to such a climbing animal as an opossum. On the anterior limbs all the five digits are provided with long sharp claws, and the pollex or thumb is but little opposable. Their numerous teeth are covered with minute sharply-pointed cusps, with which to crush the insects on which they feed, for the opossums seem to take in South America the place in the economy of nature filled in other countries by the true *Insectivora*, the hedgehogs, moles, and shrews.

The family consists of two well-recognized genera only, viz., *Didelphys*, containing all the members of the family, with the exception of the Yapock, a curious animal which forms by itself the second genus, *Chironectes*, and is distinguished from all other opossums by its webbed feet, non-tuberculated soles, and peculiar coloration. Its ground colour is light grey, with four or five sharply-contrasted brown bands passing across its head and back, giving it a very peculiar mottled appearance. It is almost wholly aquatic in its habits, living on small fish, crustaceans, and other water animals; its range extends from Guatemala to southern Brazil.

The other genus of opossums, *Didelphys*, is an extremely heterogeneous one, and has been split up into several groups, some of which perhaps ought also to be recognized as genera. The first of these consists of three or four large dull-coloured long- and coarse-haired species, with perfect marsupial pouches, large leafy ears, and greatly-developed muscular ridges on their skulls. The best known of these, and indeed of all the family, is the Virginian Opossum, *Didelphys virginiana*, an animal spread over all temperate North America; it is extremely common, being even found living in the towns, where it acts as a scavenger by night, retiring for shelter by day upon the roofs of the houses or into the sewers. It produces in the spring from six to sixteen young ones, which are placed by the mother in her pouch immediately after birth, and remain there until able to take care of themselves; the period of gestation is from fourteen to seventeen days. Another very similar species is found in central and tropical South America, and is known as the Crab-eating Opossum (*D. cancrivora*). The second group, or sub-genus, named *Metachirus*, contains a considerable number of species found all over the tropical parts of the New World. They are of medium size, with short close fur, very long, scaly, and naked tails, and have less developed ridges on their skulls. They have as a rule no pouches in which to carry their young, and the latter therefore commonly ride on their mother's back, holding on by winding their prehensile tails round hers. The accompanying woodcut represents Lord Derby's Opossum (*D. derbiana*) carrying its young in this manner.



Didelphys derbiana.

The third group is *Micoureus* (*Grymæomys* of Burmeister), differing only from *Metachirus* by the comparatively smaller size of its members and by certain slight differences in the shape of their teeth. Its best-known species is the Murine Opossum (*D. murina*), no larger than a house-mouse, of a bright-red colour, which is found as far north as central Mexico, and extends thence right down to the south of Brazil. The last sub-genus contains three or four wonderfully shrew-like species, of very small size, with short, hairy, and non-prehensile tails, not half the length of the trunk, and with wholly unridged skulls. The most striking member of the group is the Three-striped Opossum (*D. tristriata*), from Brazil, which is of a reddish-grey colour, with three clearly-defined deep-black bands down its back, very much as in some of the striped mice of Africa. This sub-genus has been named *Hemiurus* or "half-tail" by Geoffroy Saint-Hilaire (*Microdelphys* of Burmeister), and should perhaps be allowed full generic rank.

The numerous fossil remains referable to species of the *Didelphyidæ* are of special interest as showing some of the connecting links in geographical distribution between the opossums and the Australian Marsupials, now so widely and absolutely separated. They consist of the bones of a considerable number of species from the Eocene and Early Miocene deposits of central France, one or two Eocene species having also been found in southern England. These ancient opossums have been separated generically from *Didelphys* on account of certain differences in the relative sizes of the lower premolars, but as nearly the whole of the species have been formed on lower jaws only, of which some hundreds have been found, it is impossible to judge how far these differences are correlated with other dental or osteological characters. In the opinion of Dr Filhol, who has devoted considerable attention to the subject, the fossils themselves represent two genera, *Peratherium*, containing

the greater part of the species, about twenty in number, and *Amphiperatherium*, with three species only. All are comparatively small animals, few of them exceeding the size of a rat.

Besides these interesting European fossils, a certain number of Didelphian bones have been found in the caves of Brazil, but these are either closely allied to or identical with the species now living in the same region. (O. T.)

OPPELN (Polish, *Oppolie*), the chief town of a district of its own name and the seat of government for Upper Silesia, Prussia, lies on the right bank of the Oder, 50 miles to the south-east of Breslau. It contains the oldest Christian church in the district, founded at the close of the 10th century, and a ducal palace of the 15th century, on an island in the Oder. The most prominent among the other buildings are the offices of the district authorities, the town-house, the normal seminary, and the hospital. The Roman Catholic gymnasium is established in an old Jesuit college. The industries of Oppeln include the manufacture of Portland cement, soap, cigars, and lime; and a trade is carried on by rail and river in cattle, grain, and the mineral produce of the district. The population in 1880 was 14,417, of whom 10,772 were Roman Catholics. The upper classes speak German, the lower Polish.

Oppeln was already a flourishing place at the beginning of the 11th century, and after 1132 was the capital of an independent duchy, which became a fief of Bohemia in 1327, and was absorbed by the empire in 1556.

OPPENHEIM, a small town in the grand-duchy of Hesse-Darmstadt, Germany, is picturesquely situated on a hill on the left bank of the Rhine, 20 miles to the south of Mainz. It contains (1880) 3288 inhabitants, half Roman Catholics and half Protestants, who cultivate the vine and manufacture tacks, quinine, and leather.

Oppenheim, which occupies the site of the Roman castle Bauconica, was formerly much larger than at present; and in the early Middle Ages it was a free town of the empire and one of the most important members of the Rhenish League. It lost its independence in 1398, when it was given in pledge to the elector palatine. During the Thirty Years' War the town was alternately occupied by the Swedes and the Imperialists, and in 1689 it was entirely destroyed by the French under Melac. The only relic of its former importance is the church of St Catherine, one of the most beautiful Gothic edifices of the 13th and 14th centuries in Germany, recently carefully restored at the expense of Government.

OPPIAN. The literary history of the three Greek poems on fishing, hunting, and fowling respectively which have come down to us from antiquity under the name of Oppian involves several perplexing questions. According to Suidas, Eusebius, and Syncellus, the author was a native of Anazarbus or Corycus in Cilicia, and flourished in the reign of Marcus Aurelius. Athenæus also, who almost certainly wrote under Septimius Severus, speaks of Oppian as a predecessor and near contemporary. According to an anonymous biographer, he was the son of a philosopher of Anazarbus named Agesilaus, who having incurred the displeasure of Severus by neglecting to wait upon him was banished to Malta. Young Oppian accompanied his father, and by the exercise of his poetical talents obtained his recall, and was further rewarded by a piece of gold for every line he had written. He died prematurely upon his return to his native country, and was honoured by an epitaph, which has been preserved, celebrating his precocious genius, but affording no clue to his works or his date. On turning to Oppian himself we find that his poem on fish and fishing (*Halieutica*) is actually addressed to an emperor Antoninus who can have been no other than Marcus Aurelius, since the monarch's son is frequently mentioned, and the other Antonine princes were childless. The author seems to speak of himself as a Cilician. On the other hand, the poem on hunting (*Cynegetica*) is no less unmistakably addressed to the successor of Severus, Antoninus Caracalla, and the writer represents himself as a citizen of Pella or Apamea in Syria. The style of the two poems, moreover, is dissimilar, the former being polished and poetical, the latter inelegant and commonplace. If the *Cynegetica* had been the earlier this might have been explained, but the reverse is the fact. There seems no alternative, therefore, but to divide the authorship, and the allusions of the author of the *Halieutica* to Commodus make it almost certain that he must have written between the elevation of that prince to the dignity of Augustus and the death of Marcus (177-180 A.D.), while the *Cynegetica* seem to have been composed after the death of Severus (211 A.D.). The improbability of two poets of the same name and writing on such similar subjects having been such near contemporaries may be escaped by the supposition that the later writer was not really named Oppian, but has been confounded with his predecessor from their poems being transcribed together. This is the more probable as the poem on fowling (*Ixeutica*), which seems to resemble the *Cynegetica* in style, but is only extant in a prose epitome, is attributed in some MSS. to a certain Dionysius. In this case Oppian's premature death and his epitaph may be accepted as historical and genuine. The story of his deliverance of his father must be apocryphal, and the imperial reward is probably founded upon a too literal interpretation of the epithet "golden" applied to his verses.

The *Halieutica* are indeed excellent verses. Oppian has made the most of his subject, which he has adorned with all the resources of aquatic fancy and fable, and to which he has ingeniously imparted human interest by constant parallels between the existence of fishes and the pursuits and perils of human life. His matter is arranged to the best advantage: "he loves descriptions," says M. Henri Martin, "but not digressions." Though careless of fact in comparison with poetic embellishment, he has a first-hand acquaintance with his theme as a sportsman and a lover of nature. His diction is choice, his style animated, and his versification sonorous. Rhetorical display, the accumulation of detail, and an occasional inaptness in his comparisons are his only serious faults. The writer of the *Cynegetica*, who sometimes copies and spoils him, is a far inferior writer, frequently tasteless, generally awkward and dry. Some of his descriptions, however, possess merit; he is a naturalist as well as a poet, and his observation of nature is often remarkably close, although, like his predecessor, he abounds in fables. His poem seems to want a final book, in which the stratagems of the chase would have been more fully described. The poetical qualities of the *Ixeutica*, if any, have evaporated in the paraphrase; the descriptions of the fowler's snares are clear and precise.

The *Halieutica* were first printed in 1478, in the metrical Latin version of L. Lippus. The editio princeps of the original was published by Junta at Florence in 1515; the *Halieutica* and *Cynegetica* were printed together by Aldus in 1517; the *Ixeutica* did not appear till 1704. The principal modern editions are those by Schneider (Strasburg, 1776), who first distinguished between the two Oppians, and by Lehrs (Paris, 1846, along with the Bucolic poets), who adopted a number of ingenious emendations by Koechly. Copious scholia on the *Halieutica* were edited by Bussemaker (Paris, 1849). The best authorities on the literary questions connected with the Oppians are Ferdinand Peter, *Commentatio*, Zeitz, 1840; Henri Martin in the *Journal général de l'Instruction Publique*, vols. xxxi. and xxxii.; and Ausfeld, *De Oppiano*, &c., Gotha, 1876. The English translation of the *Halieutica* by Diaper, completed by Jones (Oxford, 1722), is not deficient in spirit, but much too diffuse. The French prose translations by Limes and Belin de Ballu have been superseded by Bourquin's, Coulommiers, 1877. (R. G.)

OPPIUS, CAIUS, was an intimate friend and confidant of Julius Cæsar. He managed the dictator's private affairs, and took no public office, but during the time when Cæsar was absent from Rome he, together with Balbus, exercised very great influence on public business. According to Suetonius, many authorities considered Oppius to have written the histories of the Spanish, African, and Alexandrian wars which are printed among the works of Cæsar. Niebuhr unhesitatingly assigns the African war to Oppius.

OPTICS, Geometrical. The subject of optics is so extensive that some subdivision of it is convenient if not necessary. Under the head of Light will be found a general sketch accompanied by certain developments. The wave theory and those branches of the subject which are best expounded in connexion with it are reserved for treatment in a later volume. The object of the present paper is to give some account of what is generally called geometrical optics,—a theoretical structure based upon the laws of reflexion and refraction. We shall, however, find it advisable not to exclude altogether the conceptions of the wave theory, for on certain most important and practical questions no conclusions can be drawn without the use of facts which are scarcely otherwise interpretable. Indeed it is not to be denied that the too rigid separation of optics into geometrical and physical has done a good deal of harm, much that is essential to a proper comprehension of the subject having fallen between the two stools.

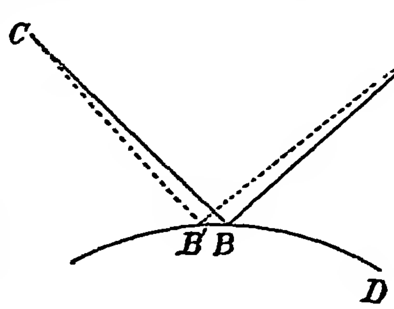


Fig. 1.

Systems of Rays in General.—In the investigation of this subject a few preliminary propositions will be useful.

If a ray AB (fig. 1) travelling in a homogeneous medium suffer reflexion at a plane or curved surface BD, the total path between any two points A, C on the ray is a minimum, *i.e.*, AB + BC is less along the actual path than it would be if the point B were slightly varied.

For a variation of B in a direction perpendicular to the plane of reflexion (that of the diagram) the truth of this statement is at once evident. For a small variation BB′ in the plane of reflexion we see that the difference AB′ − AB is equal to the projection of BB′ upon AB, and that the difference CB − CB′ is equal to the projection of BB′ upon BC. These projections are equal, since by the law of reflexion AB and BC are equally inclined to BB′, and thus the variation of the total path, AB′ + B′C − (AB + BC), vanishes.

A corresponding proposition holds good in the case of refraction. If we multiply the distances travelled in the first and second media respectively by the refractive indices appropriate to the media, the quantity so obtained is a minimum for the actual path of the ray from any point to any other. It is sufficient to consider the case of a variation of the point of passage in the plane of refraction.

In the first medium (fig. 2) $\mu AB' - \mu AB = \mu BB' \cos ABD$, and in the second medium $\mu' CB - \mu' CB' = \mu' BB' \cos CBD$. The whole variation of the quantity in question is therefore

$$BB' (\mu \cos ABD - \mu' \cos CBD).$$

Now by the law of refraction the sines of the angles of incidence and refraction are in the ratio $\mu' : \mu$, and accordingly

$$\mu \cos ABD - \mu' \cos CBD = 0.$$

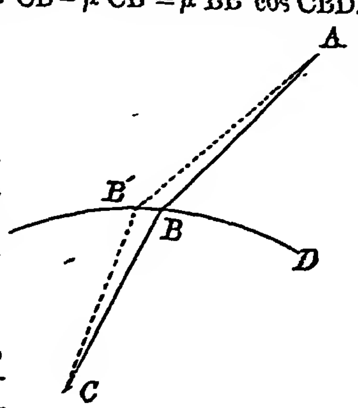

Fig. 2.

In whichever direction, therefore, the point of transition be varied, the variation of the quantity under consideration is zero. It is evident that the second proposition includes the first, since in the case of reflexion the two media are the same.

The principle of the superposition of variations now allows us to make an important extension. If the quantity, which we may denote by $\Sigma\mu s$, be a minimum for separate variations of all the points of passage between contiguous media, it is also a minimum even when simultaneous variations are admitted. However many times a ray may be reflected or refracted at the surfaces of various media, the actual path of the ray between any two points of its course makes $\Sigma\mu s$ a minimum. Even if the variations of refractive index be gradual instead of sudden, the same principle holds good, and the actual path of the ray makes $\int \mu ds$, as it would now be written, a minimum.

The principle itself, though here deduced from the laws of reflexion and refraction, is an immediate consequence of the fundamental suppositions of the wave-theory of light, and if we are prepared to adopt this point of view we may conversely deduce the laws of reflexion and refraction from the principle. The refractive index μ is inversely proportional to the velocity of propagation, and the principle simply asserts that in passing from any point to any other the light follows the shortest course, that is, the course of earliest arrival.

If two points be such that rays issuing from one of them, and ranging through a finite angle, converge to the other after any number of reflexions and refractions, the value of $\Sigma\mu s$ from one focus to the other must be the same for all the rays.

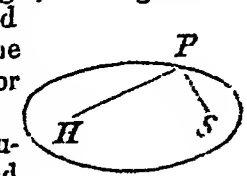

Fig. 3.

Thus, in order to condense rays issuing from one point S upon a second point H by a single reflexion (fig. 3), the reflecting surface must be such that SP + HP = const., *i.e.*, must be an ellipsoid of revolution with S and H for foci.

Again, if it be required to effect the same operation by a single refraction at the surface of a medium whose index is μ, we see that the surface (fig. 4) must be such that $SP + \mu HP = \text{const.}$

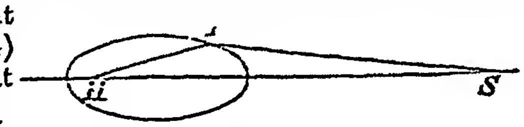

Fig. 4.

If S be at an infinite distance, *i.e.*, if the incident rays be parallel, the surface is an ellipsoid of revolution with H for focus, and of eccentricity μ^{-1} $(\mu > 1)$.

Another important proposition, obvious from the point of view of the wave-theory, but here requiring an independent proof, was enunciated by Malus. It asserts that a system of rays, emanating originally from a point, retains always the property of being normal to a surface, whatever reflexions or refractions it may undergo in traversing singly-refracting media.

Suppose that ABCDE, A′B′C′D′E′ . . . (fig. 5) are rays originally normal to a surface AA′, which undergo reflexions or refractions at BB′, CC′, &c. On every ray take points E, E′, &c., such that $\Sigma\mu s$ is the same along the courses AE, A′E′, &c. We shall prove that the rays in the final medium are normal to the surface EE′. For by hypothesis $\Sigma\mu s$ along ABCDE is the same as along A′B′C′D′E′, and, by the property proved above to attach to every ray, $\Sigma\mu s$ reckoned along the neighbouring hypo-

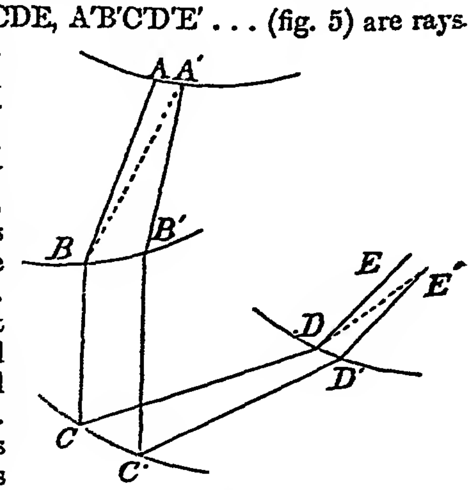

Fig. 5.

thetical course A'BCDE' is the same as along A'B'C'D'E'. Hence $\Sigma\mu s$ along A'BCDE' is the same as along ABCDE, or (on subtraction of the common part) the same along A'B, DE' as along AB, DE. But since AB is perpendicular to AA', the value along A'B is the same as along AB, and therefore the value along DE' is the same as along DE; or, since the index is the same, DE = DE', that is, EE' is perpendicular to DE. The same may be proved for every point E' which lies infinitely near E, and thus the surface EE' is perpendicular to the ray DE, and by similar reasoning to every other ray of the system. It follows that reflexions and refractions cannot deprive a system of rays of the property of being normal to a surface, and it is evident that a system issuing from a point enjoys the property initially.

Consecutive rays do not in general intersect one another; but if we select rays which cut the orthogonal surface along a *line of curvature*, we meet with ultimate intersection, the locus of points thus determined being a *caustic* curve to which the rays are tangents. Other lines of curvature of the same set give rise to similar caustic curves, and the locus of these curves is a caustic surface to which every ray of the system is a tangent. By considering the other set of lines of curvature we obtain a second caustic surface. Thus every ray of the system touches two caustic surfaces.

In the important case in which the system of rays is symmetrical about an axis, the orthogonal surface is one of revolution. The first set of lines of curvature coincide with meridians. The rays corresponding to any one meridian meet in a caustic curve, and the surface which would be traced out by causing this to revolve about the axis is the first caustic surface. The second set of lines of curvature are the circles of latitude perpendicular to the meridians. The rays which are normal along one of these circles form a cone of revolution, and meet in a point situated on the axis of symmetry. The second caustic surface of the general theorem is therefore here represented by a portion of the axis.

The character of a limited symmetrical pencil of rays is illustrated in fig. 6, in which BAC is the orthogonal surface, and HFI the caustic curve having a cusp at F, the so-called geometrical focus. The distance FD between F and the point where the extreme ray BHDG cuts the axis is called the longitudinal aberration. On account of the symmetry FD is an even function of AB. If the pencil be small, we may in general consider FD to be proportional to AB^2, although in particular cases the aberration may vanish to this order of approximation. Let us examine the nature of the sections at various points as they may be exhibited by holding a piece of paper in the solar rays converging from a common burning-glass of large aperture. In moving the paper towards the focus nothing special is observed up to the position HI, where the caustic surface is first reached. A bright ring is there formed at the margin of the illuminated area, and this gradually contracts. At D the second caustic surface DF is reached, and a bright spot develops itself at the centre. A little farther back, at EG, the area of the illuminated patch is a minimum, and its boundary is called the least circle of aberration. Farther back still the outer boundary corresponding to the extreme rays begins to enlarge, although

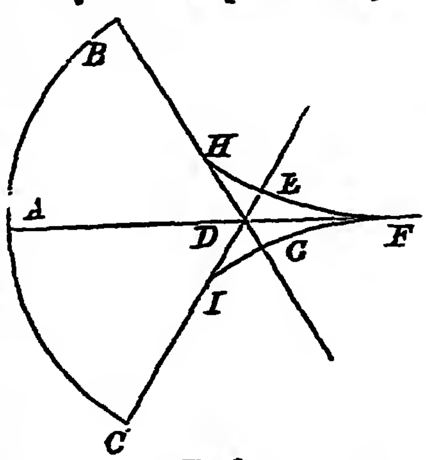

Fig. 6.

the circle of intersection with the caustic surface continues to contract. Beyond F the caustic surfaces are passed, and no part of the area is specially illuminated.

As a simple example of a symmetrical system let us take the case of parallel rays QR, OA (fig. 7), incident upon a spherical mirror AR. By the law of reflexion the angle ORq = angle ORQ = angle qOR. Hence the triangle RqO is isosceles, and if we denote the radius of the surface OA by r, and the angle AOR by α, we have

$$Oq = \frac{r}{2\cos\alpha}$$

If F be the geometrical focus, $OF = AF = \frac{1}{2}r$. If α be a small angle, the longitudinal aberration $Fq = Oq - OF = \frac{1}{2}r(\sec\alpha - 1) = \frac{1}{4}\alpha^2 r$, in which $AR = r\alpha$.

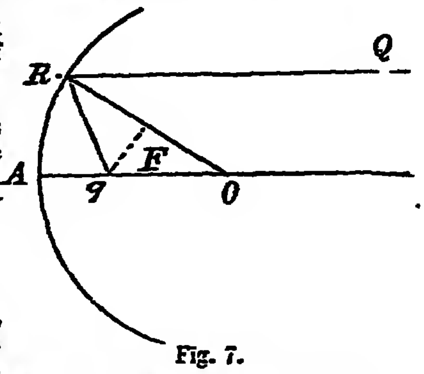

Fig. 7.

Focal Lines.—In the general case of a small pencil of rays there is no one point which can be called the geometrical focus. Consider the corresponding small area of the orthogonal surface and its two sets of lines of curvature. Of all the rays which are contiguous to the central ray there are only two which intersect it, and these will in general intersect it at different points. These points may be regarded as foci, but it is in a less perfect sense than in the case of symmetrical pencils. Even if we limit ourselves to rays in one of the principal planes, the aberration is in general a quantity of the first order in the angle of the pencil, and not, as before, a quantity of the second order. If, however, we neglect this aberration and group the rays in succession according to the two sets of lines of curvature, we see that the pencil of rays passes through two focal lines perpendicular to one another and to the central ray, and situated at the centres of curvature of the orthogonal surface. At some intermediate place the section of the pencil is circular.

It happens not unfrequently that the pencil under consideration forms part of a symmetrical system, but is limited in such a manner that the central ray of the pencil does not coincide with the axis of the system. The plane of the meridian of the orthogonal surface is called the primary plane, and the corresponding focus, situated on the caustic surface, the primary focus. The secondary focus is on the axis of symmetry through which every ray passes. The distinction of primary and secondary is also employed when the system, though not of revolution, is symmetrical with respect to a plane passing through the central ray, this plane being considered primary.

The formation of focal lines is well shown experimentally by a plano-convex lens of plate-glass held at an obliquity of 20° or 30° in the path of the nearly parallel rays, which diverge from a small image of the sun formed by a lens of short focus. The convex face of the lens is to be turned towards the parallel rays, and a piece of red glass may be interposed to mitigate the effects of chromatic dispersion.

To find the position of the focal lines of a small pencil incident obliquely upon a plane refracting surface of index μ.

The complete system of rays issuing from Q (fig. 8) and refracted at the plane surface CA is symmetrical about the line QC drawn through Q perpendicularly to the surface. Hence, if QA be the central ray of the pencil, the secondary focus q_2 lies at the intersection of the refracted ray with the axis. If ϕ be the angle of incidence, ϕ' of refraction, $AQ = u$, $Aq_2 = v_2$, then

$$\frac{v_2}{u} = \frac{\sin\phi}{\sin\phi'} = \mu \text{ ....(1).}$$

To find the position of the primary focus q_1, let QA' be a neighbouring ray in the primary plane (that of the paper) with angles of incidence and refraction $\phi + \delta\phi$ and $\phi' + \delta\phi'$, $Aq_1 = v_1$. We have

$$AA'\cos\phi = u\delta\phi, \qquad AA'\cos\phi' = v_1\delta\phi';$$

moreover, by the law of refraction,

$$\cos\phi\,\delta\phi = \mu\cos\phi'\delta\phi';$$

and thus

$$\frac{v_1}{u} = \frac{\mu\cos^2\phi'}{\cos^2\phi} \quad \text{..................(2).}$$

If the refracting surface be curved, with curvature r^{-1}, we get by similar reasoning

$$\frac{\mu\cos^2\phi'}{v_1} - \frac{\cos^2\phi}{u} = \frac{\mu\cos\phi' - \cos\phi}{r}, \quad \text{......(3);}$$

$$\frac{\mu}{v_2} - \frac{1}{u} = \frac{\mu\cos\phi' - \cos\phi}{r}, \quad \text{............(4);}$$

in which (1) and (2) are of course included as particular cases.

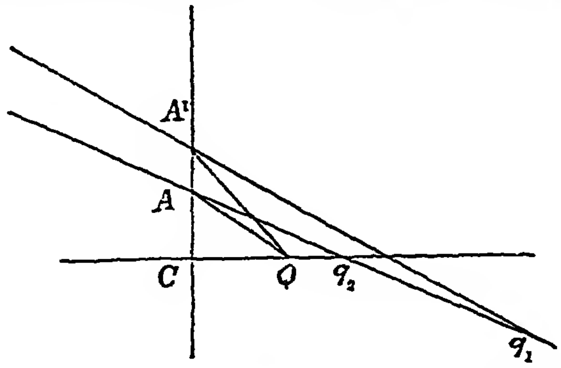

Fig. 8.

When the incidence is direct, $\cos\phi' = 1$, $\cos\phi = 1$, and $v_2 = v_1$. In this case (3) and (4) become

$$\frac{\mu}{v} - \frac{1}{u} = \frac{\mu - 1}{r}, \quad \text{..................(5).}$$

To find the positions of the focal lines of a pencil refracted obliquely through a plate of thickness t *and index* μ.

If ϕ be the angle of incidence (and emergence), ϕ' the angle of refraction of the ray QAST (fig. 9), $Sq_1 = v_1$, $Sq_2 = v_2$, $AQ = u$, we get by successive applications of (1) and (2)

$$v_1 = u + \frac{t\cos^2\phi}{\mu\cos^2\phi'}, \quad \text{..................(6);}$$

$$v_2 = u + \frac{t}{\mu\cos\phi'}, \quad \text{..................(7).}$$

If the incidence be direct,

$$v_1 = v_2 = u + \frac{t}{\mu} \quad \text{..................(8).}$$

Thus, if we interpose a plate between the eye and an object, the effect is to bring the object apparently nearer by the amount

$$\frac{(\mu - 1)t}{\mu} \quad \text{........................(9).}$$

On this result is founded a method for determining the refractive index of materials in the form of plates. A set of cross wires is observed through a magnifying glass. On interposition of the plate the glass must be drawn back through a distance given by (9) in order to recover the focus. If we measure this distance and the thickness of the plate we are in a position to determine the refractive index.

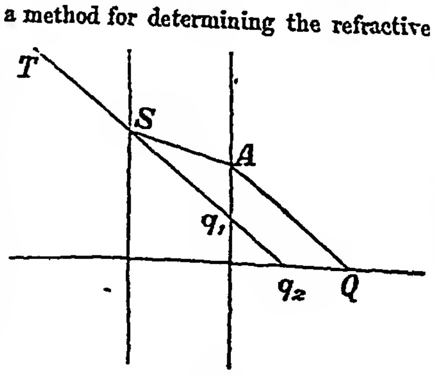

Fig. 9.

Prism.—By a prism is meant in optics a portion of transparent material limited by two plane faces which meet at a finite angle in a straight line called the edge of the prism. A section perpendicular to the edge is called a principal section.

Parallel rays, refracted successively at the two faces, emerge from the prism as a system of parallel rays. The angle through which the rays are bent is called the deviation. The deviation depends upon the angles of incidence and emergence; but, since the course of a ray may always be reversed, the deviation is necessarily a symmetrical function of these angles. The deviation is consequently a maximum or a minimum when a ray within the prism is equally inclined to the two faces, in which case the angles of incidence and emergence are equal. It is in fact a minimum; and this position of the prism is described as the position of minimum deviation, and is usually adopted for the purposes of measurement.

The relation between the minimum deviation D, the angle of the prism i, and the refractive index μ is readily found. In fig. 10 the internal angles ϕ', ψ' are each equal to $\frac{1}{2}i$. The external angles ϕ, ψ are also equal, and are connected with ϕ' by the law of refraction $\sin\phi = \mu\sin\phi'$. The deviation is $2(\phi - \phi')$. Hence

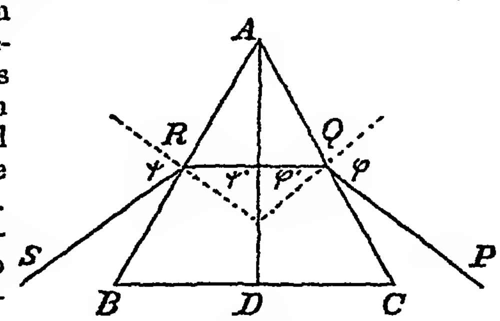

Fig. 10.

$$\mu = \frac{\sin\phi}{\sin\phi'} = \frac{\sin\frac{1}{2}(D + i)}{\sin\frac{1}{2}i};$$

and this is the formula by which the refractive index is usually determined, since both D and i can be measured with great precision.

The instrument now usually employed for this purpose is called a goniometer or spectrometer. Parallel rays are provided by a collimator, consisting of an object-glass and telescope-tube, by means of which the subject of examination, either a fine slit or a set of cross wires, is seen as if it were at an infinite distance. The parallel rays from the collimator, after reflexion from a face or refraction through the body of the prism, are received by a telescope also provided with a set of cross wires at its focus. The table upon which the prism is supported, as well as the telescope, are capable of rotation about a vertical axis, and the position of either can be read off at any time by means of graduated circles and verniers.

As a preliminary to taking an observation it is necessary to focus the collimator and telescope. The first step is to adjust the eye-lens of the telescope until the cross wires are seen distinctly and without effort. The proper position depends, of course, upon the eyesight of the observer, and is variable within certain limits in virtue of the power of accommodation. It is usually best to draw out the lens nearly to the maximum distance consistent with distinct vision. The telescope is now turned to a distant object and focused by a common motion of the cross wires and eye-lens, until both the object and the cross wires are seen distinctly at the same time. The final test of the adjustment is the absence of a relative motion when the eye is moved sideways across the eye-piece. The collimator is now brought opposite to the telescope and adjusted until the cross wires in its focus behave precisely like the distant object.

To measure the angle of a prism it may be placed with its edge vertical upon the table, in a symmetrical position with respect to the collimator (fig. 11). The telescope is then successively brought into such positions that the cross wires of the telescope coincide with the cross wires of the collimator when seen by reflexion in the two faces. The difference of the readings is twice the angle of the prism.

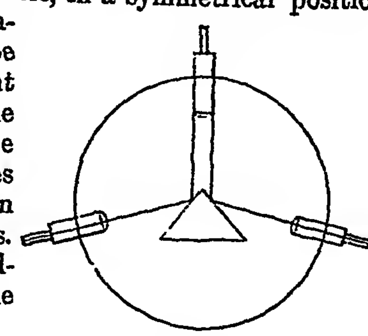

Fig 11.

Another method is also often employed in which the telescope is held fixed and the prism is rotated. The angle between the two positions of the table found by use in succession of the two faces is the supplement of the angle of the prism.

Suppose next that we wish to determine D for the given prism and for sodium light. The slit of the collimator is backed by a sodium flame, the telescope is adjusted for direct vision of the slit, and the reading taken. The prism is now placed upon the table, and rotated until the deviation of the light from its original direction when seen through the prism is a minimum. The difference of the readings for the two positions of the telescope is the value of D. The angle to be observed may be doubled by using the deviation in both directions. In this case no direct reading in the absence of the prism is required.

The following table of indices of refraction is taken from Watt's *Dictionary of Chemistry*, article "Light."

Name of Substance.	Index of Refraction.	Name of Substance.	Index of Refraction.
Chromate of lead	2·50 to 2·97	Phosphoric acid	1·534
Diamond	2·47 to 2·75	Sulphate of copper ..	1·531 to 1·552
Phosphorus..........	2·224	Canada balsam	1·532
Glass of antimony ..	2·216	Citric acid	1·527
Sulphur (native)	2·115	Crown glass	1·525 to 1·534
Zircon	1·95	Nitre................	1·514
Borate of lead	1·866	Plate glass	1·514 to 1·542

To determine the index of refraction of a liquid it must of course be placed in a hollow prism, whose faces are formed of some transparent material, usually of glass. The following results of Dale and Gladstone show the influence of temperature upon the refracting power of some important liquids. They relate to the soda flame, or the line D in the solar spectrum.

Temperature.	Bisulphide of Carbon.	Water.	Ether.	Alcohol Absolute.
0°	1·6442	1·3330	..	..
10°	1·6346	1·3327	1·3592	1·3658

Refractive Indices of Bisulphide of Carbon for the several Fixed Lines.

Temperature.	A	B	D	E	F	G
11°	1·6142	1·6207	1·6333	1·6465	1·6584	1·6836
36°·5	1·5945	1·6004	1·6120	1·6248	1·6362	1·6600
Difference	0·0197	0·0203	0·0213	0·0217	0·0222	0·0236

The rapid alteration of refractive power with temperature is a serious obstacle to the use of bisulphide of carbon prisms for exact purposes. Not only does the dispersive power vary from day to day, but inequalities of temperature in the various parts of the liquid at any one moment disturb the optical uniformity, and are thus the cause of bad definition. A difference of 1° Cent. alters the index about as much as a change in the light from one of the two D lines to the other, so that a variation of one degree within the prism may be expected to prevent the satisfactory resolution of this double line.

Excellent results have recently been obtained by Liveing with prisms containing aqueous solution of iodide of potassium and mercury. This liquid can be brought up to a density as high as three times that of water, and gives a powerful dispersion. Some difficulty has, however, been experienced in finding a suitable cement for the faces. Bisulphide of carbon prisms are usually cemented with a mixture of glue and treacle.

For many purposes the deviation of the light in passing through an ordinary prism is objectionable. In such cases recourse may be had to *direct vision* prisms (fig. 12), in which two materials, usually flint and crown, are so combined that the refractions are equal and opposite for a selected ray, while the dispersions are as unequal as may be. The direct vision prism may be contrasted with the achromatic lens (see LIGHT). In the first the object is to obtain dispersion without refraction, and in the second to obtain refraction without dispersion.

Fig. 12.

Compound prisms, composed of a flint between two crowns, are also made, in which the action of the crown is not carried so far as to destroy the deviation due to the flint. By this construction a larger angle is admissible for the more dispersive material, but it is not clear that any sufficient advantage is gained.

The principle of the compound prism is carried to its limit by employing media of *equal* refracting power for the part of the spectrum under examination. For this purpose bisulphide of carbon and flint glass may be chosen. With Chance's "dense flint" the refractions are the same, and the difference of dispersions is about as great as for "double-extra-dense flint" and crown. A dozen glass prisms of 90° may be cemented in a row on a strip of glass and immersed in a tube of bisulphide of carbon closed at the ends by glass plates. To vary the ray, which passes without deviation, ether may be mixed with the bisulphide.[2]

The formation of a pure spectrum, which may be either thrown upon a screen or photographic plate, or received at once by the eye armed with a magnifier, has been explained under LIGHT. It sometimes happens that the object is not to see the spectrum itself, but to arrange a field of view uniformly illuminated with approximately homogeneous light. For this purpose the pure spectrum is received upon a screen perforated by a narrow slit parallel to the fixed lines. The light which passes this second slit (eye-slit) is approximately homogeneous. Suppose that it corresponds to the red of the spectrum. The eye, placed immediately behind the eye-slit, receives only red light, and, if focused upon the prism, sees a red field of view whose brightness is uniform if the light falling in different directions upon the original slit be uniform. To secure the fulfilment of the last condition we may use the light from an overcast sky, or that of the sun reflected from a large surface of white paper. If it be desired to work by artificial light, an Argand gas flame diffused by an opal globe will be found suitable. When the adjustments are correct the tint should be perfectly uniform. Any difference of colour on the two sides of the field of view is an indication that the screen is not in its proper place.

The most important application of this arrangement is to the investigation of compound colours, as carried out by Maxwell.[3] If light be admitted also through a second slit,

[1] *Proc. Roy. Soc.*, June 1877.

[2] See "Investigations in Optics," *Phil. Mag.*, January 1880.

[3] "Theory of Compound Colours," *Phil. Trans.*, 1860.

displaced laterally from the position occupied by the first, a second spectrum overlapping the former will be thrown upon the screen, and a second kind of light will be admitted to the eye. In this way we may obtain a field of view lighted with a mixture of two or more spectrum colours, and we may control the relative proportions by varying the widths of the slits. For instance, by mixing almost any kind of red with any kind of green not inclining to blue we may match the brightest yellows, proving what so many find it difficult to believe, that yellow is a compound colour. In Maxwell's systematic examination of the spectrum, mixtures of three colours were used, and the proportions were adjusted so as to match the original white light incident upon the apparatus.

A similar arrangement (with one original slit) was employed by Helmholtz in his examination of a fundamental question raised by Brewster. The latter physicist maintained that there was abundant evidence to show that light of definite refrangibility was susceptible of further analysis by absorption, so that the colour of light (even of given brightness) could not be defined in terms of refrangibility or wave-length alone. The appearances which misled Brewster have since been explained as the effect of contrast or of insufficient purity. It is obvious that light, *e.g.*, from the red end of the spectrum, may be contaminated with light from some other part, say the yellow, in such proportion that though originally entirely preponderant it may fall into the second place under the action of a medium very much more transparent to yellow than to red. To obtain light of sufficient purity for these experiments Helmholtz found it advisable to employ a double prismatic analysis. A spectrum is first thrown upon a screen perforated by a slit in the manner already described. The light which penetrates the second slit, already nearly pure, is caused to pass a second prism by the action of which any stray light is thrown aside. Using such doubly purified light, Helmholtz found the colour preserved, whatever absorbing agents were brought into play. Light of given refrangibility may produce a variety of *effects*, visual, thermal, or chemical, but (apart from polarization) it is not itself divisible into parts of different kinds. If yellow light produces the compound sensation of yellow, we are to seek the explanation in the constitution of the retina, and not in the divisibility of the light.

In all accurate work with the prism the use of a collimating lens to render the incident light parallel is a matter of necessity. If the incident rays diverge from a point at a finite distance, the pencil after emergence will be of a highly complicated character. There are, however, cases in which a collimator is dispensed with, and thus it is a problem of interest to find the foci of a thin pencil originally diverging from a point at a moderate distance. Even when a collimator is employed, the same problem presents itself whenever the focusing is imperfect. For the sake of simplicity the pencil is supposed to pass so near the edge of the prism that the length of path within the glass may be neglected in comparison with the distances of the foci.

We denote as usual the angles of incidence and emergence by ϕ, ψ, and the corresponding angles within the glass by ϕ', ψ'. The distance AQ from the edge of the prism to original source is denoted by u; the corresponding distances for the primary and secondary foci q_1, q_2 by v_1, v_2. By successive applications of the results already proved for a single refraction, we get

$$v_2 = u, \quad v_1 = \frac{\cos^2\phi' \cos^2\psi}{\cos^2\phi \cos^2\psi'} u \quad \text{............(1)};$$

so that

$$\frac{v_1}{v_2} = \frac{\cos^2\phi' \cos^2\psi}{\cos^2\phi \cos^2\psi'} = \frac{(\mu^2-1)\tan^2\phi + \mu^2}{(\mu^2-1)\tan^2\psi + \mu^2} \quad \text{......(2)}.$$

In order that the primary and secondary foci may coincide we must have $\psi = \phi$; that is to say, the ray must pass with minimum deviation. This is sometimes given as a reason why this arrangement should be adopted in spectroscopes; but in reality, since the slit is parallel to the edge of the prism, a slight elongation in this direction of the image of a point is without detriment to the definition. Hence a good image will be seen when the telescope is adjusted for the primary focus; and it is not clear that any improvement would arise from coincidence of the two foci, the question being in fact one of aberration. The position of minimum deviation is, however, usually adopted for the sake of definiteness, and sometimes it is convenient that the fixed lines and the extremities of the slit (or the markings produced by dust) should be in focus together.

The deviation is a symmetrical function of ϕ and ψ, and therefore is not altered by an interchange of these angles. The corresponding values of v are thus by (1) reciprocals, and their product is equal to u^2. This principle has been ingeniously applied by Schuster[1] to the adjustment for focus of the telescope and collimator of a spectroscope. The telescope is so placed that the deviation necessary to bring the object upon the cross wires is greater than the minimum, and the prism is adjusted in azimuth until the effect is produced, that position being chosen for which the angle of incidence is greater than the angle of emergence, so that v_1 is greater than u. After focusing the telescope the prism is turned into the other position which gives the same deviation, and the *collimator* is focused, the telescope remaining untouched. The prism is next brought back to the first position, and the telescope is again focused. A few repetitions of this operation, always focusing the telescope in the first position of the prism and the collimator in the second, will bring both into perfect adjustment for parallel rays.

Lenses.—The usual formula for the focal length of lenses (vol. xiv. p. 593),

$$\frac{1}{f} = (\mu - 1)\left(\frac{1}{r} - \frac{1}{s}\right) \text{.............. ...(1)},$$

ignores the fact that the various parts of a lens bounded by spherical surfaces have not the same focus, and is applicable in strictness only when the aperture is small. It is not necessary here to repeat the process by which (1) is usually obtained, but before passing on to give the formulæ for the aberration of lenses it may be well to exhibit the significance of (1) from the point of view of the wave-theory.

Taking the case of a convex lens of glass, let us suppose that parallel rays DA, EC, GB (fig. 13) fall upon the lens ACB, and are collected by it to a focus at F. The points D, E, G, equally distant from ACB, lie upon a front of the wave before it impinges upon the lens. The focus is a point at which the different parts of the wave arrive at the same time, and that such a point can exist depends upon the fact that the propagation is slower in glass than in air. The ray ECF is retarded from having to pass through the thickness (t) of glass by the amount $(\mu - 1)t$. The ray DAF, which traverses only the extreme edge of the lens, is retarded merely on account of the crookedness of its path, and the amount of the retardation is measured by AF − CF. If F is a focus these retardations must be equal, or

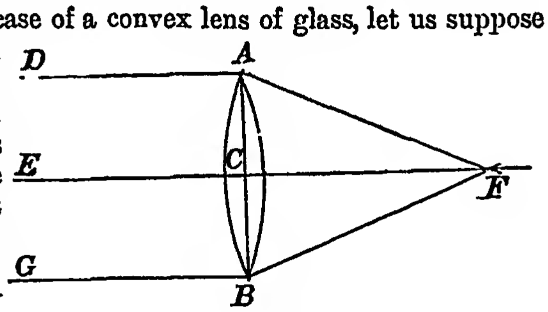

Fig. 13.

$$AF - CF = (\mu - 1)t.$$

Now if y be the semi-aperture AC of the lens, and f be the focal length CF,

$$AF - CF = \sqrt{\{f^2 + y^2\}} - f = \tfrac{1}{2}\frac{y^2}{f} \text{ approximately,}$$

whence

$$f = \frac{y^2}{2(\mu - 1)t} \text{ ....(2)}.$$

In the case of plate-glass $\mu - 1 = \frac{1}{2}$ nearly, and then the rule (2) may be thus stated: *the semi-aperture is a mean proportional between the focal length and the thickness.* The form (2) is in general the more significant, as well as the more practically useful, but we may of course express the thickness in terms of the curvatures and semi-aperture by means of

$$t = \tfrac{1}{2}y^2\left(\frac{1}{r} - \frac{1}{s}\right).$$

[1] *Phil. Mag.*, February 1879.

In the preceding statement it has been supposed for simplicity that the lens comes to a sharp edge. If this be not the case we must take as the thickness of the lens the *difference* of the thicknesses at the centre and at the circumference. In this form the statement is applicable to concave lenses, and we see that the focal length is positive when the lens is thickest at the centre, but negative when the lens is thickest at the edge.

To determine practically the focal length of a convex lens we may proceed in several ways. A convenient plan is to set up a source of light Q (fig. 14) and a screen q at a distance exceeding four times the focal length, and to observe the two positions of the lens A, A′ at which the source is in focus upon the screen. These positions are symmetrically situated, and the distance between them is observed. Thus

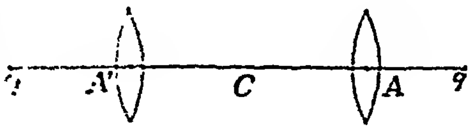

Fig. 14.

$$AQ = \tfrac{1}{2}Qq + \tfrac{1}{2}AA', \qquad Aq = \tfrac{1}{2}Qq - \tfrac{1}{2}AA'.$$

Now

$$\frac{1}{AQ} - \frac{1}{Aq} = \frac{1}{f},$$

so that

$$f = \frac{AQ \cdot Aq}{AQ + Aq} = \tfrac{1}{4}\frac{Qq^2 - AA'^2}{Qq}.$$

From the measured values of Qq and AA', f can be deduced.

If A and A′ coincide, the conjugate foci Q and q are as close as possible to one another, and then $f = \tfrac{1}{4}Qq$.

The focal length on a concave lens may be found by combining it with a more powerful convex lens of known focus.

Aberration of Lenses.—The formula (1) determines the point at which a ray, originally parallel to the axis and at but a short distance from it, crosses the axis after passage through the lens. When, however, the ray considered is not quite close to the axis, the point thus determined varies with the distance y. In the case of a convex lens the ray DH (fig. 15), distant HC ($=y$) from the axis,

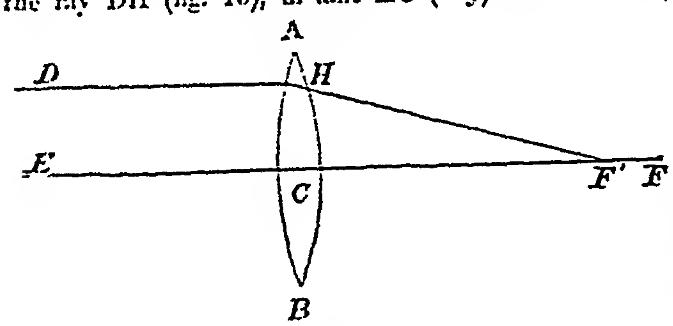

Fig. 15.

crosses it after refraction at a point F′ which lies nearer to the lens than the point F determined by (1), and corresponding to an infinitely small value of y. The distance F′F is called the *longitudinal aberration* of the ray, and may be denoted by δf.

The calculation of the longitudinal aberration as dependent upon the refractive index (μ) and the anterior and posterior radii of the surfaces (r, s) is straight forward, but is scarcely of sufficient interest to be given at length in a work like the present. It is found that

$$-\delta f : \frac{y^2}{f} = \frac{\mu-1}{2\mu^2}\left\{\frac{1}{r^3} + \left(\frac{\mu+1}{f} - \frac{1}{s}\right)\left(\frac{1}{f} - \frac{1}{s}\right)^2\right\}f^3 \ldots (3),$$

r, s, and f being related as usual by (1).

The first question which suggests itself is whether it is possible so to proportion r and s that the aberration may vanish. Writing for brevity R, S, F respectively for r^{-1}, s^{-1}, f^{-1}, and taking $G = \frac{\mu F}{\mu - 1}$, so that $-S = (G/\mu) - R$, we get

$$\frac{1}{r^3} + \left(\frac{\mu+1}{f} - \frac{1}{s}\right)\left(\frac{1}{f} - \frac{1}{s}\right)^2 = G\{R^2(\mu+2) - RG(2\mu+1) + \mu G^2\}$$
$$= G\left\{\sqrt{(\mu+2)}.R - \frac{(2\mu+1)G}{2\sqrt{(\mu+2)}}\right\}^2 + \frac{\mu^3F^3}{(\mu-1)^3}\,\frac{4\mu-1}{4(\mu+2)} \ldots (4).$$

Since $\mu > 1$, both terms are of the same sign; and thus it appears that the *aberration can never vanish*, whatever may be the ratio of r to s. Under these circumstances all that we can do is to ascertain for what form of lens the aberration is a minimum, the focal length and aperture being given. For this purpose we must suppose that the first term of (4) vanishes, which gives

$$r = \frac{2(\mu+2)(\mu-1)}{\mu(2\mu-1)}f \ldots\ldots\ldots\ldots (5).$$

The corresponding value of $-s$ is

$$-s = \frac{2(\mu+2)(\mu-1)}{4+\mu-2\mu^2}f \ldots\ldots\ldots\ldots (6);$$

so that

$$-s : r = \frac{\mu(2\mu-1)}{4+\mu-2\mu^2} \ldots\ldots\ldots\ldots (7).$$

In the case of plate-glass $\mu = 1{\cdot}5$ nearly, and then from (5), (6), (7)

$$r = \frac{7}{12}f, \quad -s = \frac{7}{2}f, \quad -s : r = 6:1.$$

Both surfaces are therefore convex, but the curvature of the anterior surface (that directed towards the incident parallel rays) is six times the curvature of the posterior surface. By (3) the outstanding aberration is

$$\delta f = -\frac{15}{14}\frac{y^2}{f} \ldots\ldots\ldots\ldots (8).$$

The use of a plano-convex lens instead of that above determined does not entail much increase of aberration. Putting in (3) $s = \infty$, and therefore by (1) $r = \frac{1}{2}f$, we get

$$\delta f = -\frac{7}{6}\frac{y^2}{f} \ldots\ldots\ldots\ldots (9).$$

This is on the supposition that the curved side faces the parallel rays. If the lens be turned round so as to present the plane face to the incident light we have $r = \infty$, $-s = \frac{1}{2}f$, and then

$$\delta f = -\frac{9}{2}\frac{y^2}{f} \ldots\ldots\ldots\ldots (10),$$

nearly four times as great.

For a somewhat higher value of μ the plano-convex becomes the form of minimum aberration. If $s = \infty$ in (6), $4 + \mu - 2\mu^2 = 0$, whence $\mu = 1{\cdot}69$.

If μ be very great, we see from (5) and (6) that r and s tend to become identical with f.

For the general value of μ the minimum aberration corresponding to (7) is by (4)

$$-\delta f : \frac{y^2}{f} = \frac{\mu(4\mu-1)}{8(\mu-1)^2(\mu+2)} \ldots\ldots\ldots (11).$$

The right-hand member of (11) tends to diminish as μ increases, but it remains considerable for all natural substances. If $\mu = 2$,

$$-\delta f : \frac{y^2}{f} = \frac{7}{16}.$$

Oblique Pencils.—Hitherto we have supposed that the axis of the pencil coincides with the axis of the lens. If the axis of the pencil, though incident obliquely, pass through the centre of the lens, it suffers no deviation, the surfaces being parallel at the points of incidence and emergence. In this case the primary and secondary foci are formed at distances from the centre of the lens which can only differ from the distance corresponding to a direct pencil by quantities of the second order in the obliquity. Hence, if the obliquity be moderate, we may use the same formulæ for oblique as for direct pencils.

The consideration of excentrical pencils leads to calculations of great complexity, upon which we do not enter.

Chromatic Aberration.—The operation of simple lenses is much interfered with by the variation of the refractive index with the colour of the light. The focal length is decidedly less for blue than for red light, and thus in the ordinary case of white light it is impossible to obtain a perfect image, however completely the spherical aberration may be corrected. From the formula for the focal length we see that

$$\frac{\delta f}{f^2} = -\delta\mu\left(\frac{1}{r} - \frac{1}{s}\right) = -\frac{\delta\mu}{\mu-1}\,\frac{1}{f},$$

so that

$$-\delta f = \frac{\delta\mu}{\mu-1}f;$$

or the longitudinal chromatic aberration varies as the focal length and as the dispersive power of the material com-

posing the lens. The best image will be formed at a position midway between the two foci, and the diameter d of the circle over which the rays are spread bears the same ratio to the semi-aperture of the lens (y) that δf bears to f. Hence

$$d = \frac{\delta\mu}{\mu - 1} y.$$

The diameter of the circle of chromatic aberration is thus proportional to the aperture and *independent of the focal length*; and since the linear dimensions of the image are proportional to the focal length, the confusion due to chromatic aberration may be considered to be inversely as the focal length. Before the invention of the achromatic object-glass this source of imperfect definition was by far the most important, and, in order to mitigate its influence, telescopes were made of gigantic length. Even at the present day the images of large so-called achromatic glasses are sensibly impaired by secondary chromatic aberration, the effect of which is also directly as the aperture and inversely as the focal length.

Achromatic Object-glasses.—It has been shown in vol. xiv. p. 595 that the condition of achromatism for two thin lenses placed close together is

$$\frac{\delta\mu}{\mu - 1}\frac{1}{f} + \frac{\delta\mu'}{\mu' - 1}\frac{1}{f'} = 0 \quad \ldots\ldots\ldots\ldots\ldots (1),$$

in which f, f' are the focal lengths of the two lenses, and $\delta\mu/(\mu - 1)$, $\delta\mu'/(\mu' - 1)$ the dispersive powers of the two kinds of glass. In practice crown and flint glass are used, the dispersive power of the flint being greater than that of the crown. Thus f' is negative and numerically greater than f, so that the combination consists of a convex lens of crown and a concave lens of flint, the converging power of the crown overpowering the diverging power of the flint. When the focal length F of the combination is given, the focal lengths of the individual lenses are determined by (1) in conjunction with

$$\frac{1}{F} = \frac{1}{f} + \frac{1}{f'} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots (2).$$

The matter, however, is not quite so simple as the above account of it might lead us to suppose. In consequence of what is called the irrationality of spectra, the ratio of dispersive powers of two media is dependent upon the parts of the spectrum which we take into consideration. Whatever two rays of the spectrum we like to select, we can secure that the compound lens shall have the same focal length for these rays, but we shall then find that for other rays the focal length is slightly different. In the case of a single lens the focal length continually diminishes as we pass up the spectrum from red to violet. By the use of two lenses the spectrum, formed as it were along the axis, is doubled upon itself. The focal length is least for a certain ray, which may be selected at pleasure. Thus in the ordinary achromatic lens, intended for use with the eye, the focal length is a minimum for the green, and increases as we pass away from the green, whether towards red or towards blue. Stokes has shown that the secondary colour gives a sharp test of the success of the achromatizing process.

"The secondary tints in an objective are readily shown by directing the telescope to a vertical line separating light from dark, such as the edge of a chimney seen in the shade against the sky, and covering half the object-glass with a screen having a vertical edge. So delicate is this test that, on testing different telescopes by well-known opticians, a difference in the mode of achromatism may be detected. The best results are said to be obtained when the secondary green is intermediate between green and yellow. This corresponds to making the focal length a minimum for the brightest part of the spectrum.

"To enable me to form a judgment as to the sharpness of the test furnished by the tint of the secondary green, as compared with the performance of an object-glass, I tried the following experiment. A set of parallel lines of increasing fineness was ruled with ink on a sheet of white paper, and a broader black object was laid upon it as well, parallel to the lines. The paper was placed, with the black lines vertical, at a considerable distance on a lawn, and was viewed through two opposed prisms, one of crown glass and the other of flint, of such angles as nearly to achromatize each other in the positions of minimum deviation, and then through a small telescope. The achromatism is now effected, and varied in character, by moving one of the prisms slightly in azimuth, and after each alteration the telescope was focused afresh to get the sharpest vision that could be had. I found that the azimuth of the prism was fixed within decidedly narrower limits by the condition that the secondary green should be of such or such a tint, even though no attempt was made to determine the tint otherwise than by memory, than by the condition that the vision of the fine lines should be as sharp as possible. Now a small element of a double object-glass may be regarded, so far as chromatic compensation is concerned, as a pair of opposed prisms; and therefore we may infer that the tint of the secondary green ought to be at the very least as sharp a test of the goodness of the chromatic compensation as the actual performance of the telescope."[1]

In the case of photographic lenses the conditions of the problem are materially different. It is usually considered to be important to secure "coincidence of the visual and chemical foci," so that the sensitive plate may occupy the exact position previously found by the eye for the ground glass screen. For this purpose the ray of minimum focus must be chosen further up in the spectrum. If, however, the object be to obtain the sharpest possible photographs, coincidence of visual and chemical foci must be sacrificed, the proper position for the sensitive plate being found by trial. The middle of the chemically-acting part of the spectrum, which will vary somewhat according to the photographic process employed, should then be chosen for minimum focus.

When the focal lengths of the component lenses have been chosen, it still remains to decide upon the curvatures of the individual faces. Between the four curvatures we have at present only two relations, and thus two more can be satisfied. One of these is given by the condition that the first term in the expression for the aberration—that proportional to the square of the aperture—shall vanish for parallel rays. As to the fourth condition, various proposals have been made. If equal and opposite curvatures are given to the second and third surfaces, the glasses may be cemented together, by which some saving of light is effected. Herschel proposed to make the aberration vanish for nearly parallel, as well as for absolutely parallel, rays. This leads to a construction nearly agreeing with that adopted by Fraunhofer.

The following results are given by Herschel[2] for the radii of the four surfaces, corresponding to various dispersive powers, and to mean refractive indices 1·524 (crown) and 1·585 (flint). The focal length of the combination is taken equal to 10, and, as well as the radii, is measured in arbitrary units; so that all the numbers in the table (with the exception of the first column) may be changed in any proportion.

Ratio of Dispersive Powers.	Radius of First Surface. +	Radius of Second Surface. —	Radius of Third Surface. —	Radius of Fourth Surface. —	Focal Length of Crown Lens. +	Focal Length of Flint Lens. —
·50	6·7485	4·2827	4·1575	14·3697	5·0	10·0000
·55	6·7184	3·6332	3·6006	14·5353	4·5	8·1818
·60	6·7069	3·0488	3·0640	14·2937	4·0	6·6667
·65	6·7316	2·5208	2·5565	13·5709	3·5	5·3846
·70	6·8279	2·0422	2·0831	12·3154	3·0	4·2858
·75	7·0816	1·6073	1·6450	10·5186	2·5	3·3333

The general character of the combination is shown in fig. 16.

The radii of the first and fourth surfaces within practical limits are so nearly constant that Herschel lays down

[1] *Proc. Roy. Soc.*, June 1878.
[2] *Phil. Trans.*, 1821.

the following rule as in all probability sufficiently exact for use. A double object-glass will be free from aberration, provided the radius of the exterior surface of the crown lens be 6·720 and of the flint 14·20, the focal length of the combination being 10·000, and the radii of the interior surface being computed from these data, by the formulæ given in all elementary works on optics, so as to make the focal lengths of the two glasses in the direct ratio of their dispersive powers.

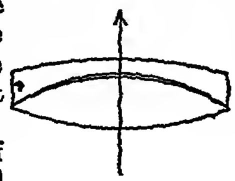

Fig. 16.

Numerous experiments have been made with the view of abolishing the secondary spectrum. Theoretically, if three different kinds of glasses are combined it will generally be possible to make the focal lengths of the combination equal for any *three* selected rays of the spectrum. Or the ingredients of one of the glasses may be mixed in such proportions as to suit the requirements of the problem when combined with crown. In this way Stokes has succeeded in constructing a small object-glass free from secondary colour, but it is doubtful whether the practical difficulties could be overcome in the construction of a large object-glass, where alone the outstanding chromatic aberration is important.

The practical optician is not limited to spherical surfaces, and the final adjustment of the aberration of large object-glasses is controlled by the action of the polishing tool. It is understood that some of the best makers apply a local correction, according to the methods developed by Foucault for mirrors. The light from a natural or artificial star is allowed to fall upon the lens. At the focus is placed a small screen, which is gradually advanced so as to cut off the light. The eye is immediately behind the screen and is focused upon the lens. If there are no imperfections the illumination falls off very suddenly, the surface of the mirror passing from light to dark through a nearly uniform grey tint. If, however, from uniform aberration, or from local defects, any of the light goes a little astray, the corresponding parts of the surface will show irregularities of illumination during the passage of the screen, and in this manner a guide is afforded for the completion of the figuring.

Töppler[1] has developed the idea of Foucault into a general method for rendering visible very small optical differences. Instead of a mere point of light, it is advisable to use as source an aperture (backed by a bright flame) of sensible size, and bounded on one side by a straight edge. An image of this source is formed at a considerable distance by a lens of large aperture and free from imperfections, and in the plane of the image is arranged a screen whose edge is parallel to the straight edge of the image, and can be advanced gradually so as to coincide with it. Behind this screen comes a small telescope through which the observer examines the object placed near the lens. When the light is just cut off by the advancing screen, the apparatus is in the most sensitive state, and the slightest disturbance of the course of the rays is rendered evident. To show the delicacy of the arrangement Töppler introduced into the cone of light a small trough with parallel glass sides containing distilled water. A syphon dipped under the surface and discharged distilled water from another vessel, and it was found almost impossible so to control the temperatures that the issuing jet should remain invisible. Not only were sound-waves in air, generated by electric sparks, rendered visible, but their behaviour when reflected from neighbouring obstacles was beautifully exhibited.

An apparatus on this principle may often be employed with advantage in physical demonstrations,—for instance, for the exhibition of the changes of density in the neighbourhood of the electrodes of a metallic solution undergoing electrolysis. The smallest irregularity that could be rendered visible would be such as would retard transmitted light by a moderate fraction of the wave-length.[2]

In objectives for photographic use the requirements are in many respects different from those most important in the case of telescopes. A flat field, a wide angle of view—in some cases as much as 90°—freedom from distortion, and a great concentration of light are more important than a high degree of definition. As a rule, photographs are not subjected to the ordeal of a high magnifying power. Usually the picture includes objects at various distances from the camera, which cannot all be in focus at once. That the objects at one particular distance should be depicted with especial sharpness would often be rather a disadvantage than otherwise. A moderate amount of "diffusion of focus" is thus desirable, and implies residual aberration. In some lenses an adjustment is provided by means of which the diffusion of focus may be varied according to the circumstances of the case.

For landscapes and general purposes a so-called single lens is usually employed. This, however, for the sake of achromatism, is compounded of a flint and a crown cemented together; or sometimes three component lenses are used, the flint being encased in two crowns, one on each side. To get tolerable definition and flatness of field a stop must be added, whose proper place is some little distance in front of the lens.

For portraiture, especially before the introduction of the modern rapid dry plates, a brilliant image was a necessity. This implies a high ratio of aperture to focal length, which cannot be attained satisfactorily with any form of single lens. To meet the demand, Petzval designed the "portrait-lens," in which two achromatic lenses, placed at a certain distance apart, combine to form the image. This construction is so successful that the focal length is often no more than three times the available aperture. When stops are employed to increase the sharpness and depth of focus they are placed *between* the lenses.

Vision through a Single Lens.—A single lens may be used to improve the vision of a defective eye, or as a magnifying glass. A normal eye is capable of focusing upon objects at any distance greater than about 8 inches. The eyes of a short-sighted person are optically too powerful, and cannot be focused upon an object at a moderate distance. The remedy is of course to be found in concave glasses. On the other hand, persons beyond middle life usually lose the power of seeing near objects distinctly, and require convex glasses.

A not uncommon defect, distinct from mere short or weak sight, is that known as astigmatism. In such cases the focal length varies in different planes, and at no distance is the definition perfect. Many people, whose sight would not usually be considered inferior, are affected by astigmatism to a certain extent. If a set of parallel black lines ruled upon white paper be turned gradually round in its own plane, it will often be seen more distinctly and with greater contrast of the white and black parts in one azimuth than in another. When the focal line on the retina is parallel to the length of the bar, the definition (as in the case of the spectroscope) is not much prejudiced, but it is

[1] *Pogg. Ann.*, cxxxi. 1867.

[2] Even when the optical differences are not small it is well to remember that transparent bodies are only visible in virtue of a variable illumination. If the light falls equally in all directions, as it might approximately do for an observer on a high monument during a thick fog, the edge of (for example) a perfectly transparent prism would be absolutely invisible. If a spherical cloud, composed of absolutely transparent material, surround symmetrically a source of light, the illumination at a distance would not be diminished by its presence.

otherwise when the bars are turned through a right angle so as to be perpendicular to the focal line.

In extreme cases a remedy may be applied in the form of glasses of different curvatures in perpendicular planes, so adjusted both in form and position as to compensate the corresponding differences in the lens of the eye.

The use of a lens as a magnifier has been explained under MICROSCOPE. The simplest view of the matter is that the lens, consistently with good focusing, allows of a nearer approach, and therefore of a higher visual angle, than would otherwise be possible.

Telescope, &c.—In a large class of optical instruments an *image* of the original object is first formed, and this image is examined through a magnifier. If we use a single lens merely for the latter purpose, the field of view is very restricted. A great improvement in this respect may be effected by the introduction of a *field*-lens. The ideal position for the field-lens is at the focal plane of the object-glass. The image is then entirely uninfluenced, and the only effect is to bend round the rays from the margin of the field which would otherwise escape, and to make them reach the eye-lens, and ultimately the eye. If the field-lens and the eye-lens have nearly the same focal length an image of the object-glass will be formed upon the eye-lens, and through this small image will pass every ray admitted by the object-glass and field-lens.

However, to obtain a sufficient augmentation of the field of view it is not necessary to give the field-lens the exact position above mentioned, and other considerations favour a certain displacement. For example, it is not desirable that dust and flaws on the field-lens should be seen in focus. In Huygens's eye-piece the field-lens is displaced from its ideal position *towards* the object-glass. In Ramsden's eye-piece, on the other hand, the focal plane of the object-glass is outside the system. This eye-piece has the important advantage that cross wires can be placed so as to coincide with the image as formed by the object-glass. The component lenses of a Ramsden's eye-piece are sometimes achromatic. For further particulars, with diagrams, on the subject of eye-pieces, see MICROSCOPE.

In large telescopes the object-glass is often replaced by a mirror, which may be of speculum metal, or of glass coated chemically with a very thin layer of polished silver. The mirror presents the advantage (especially important for photographic applications) of absolute achromatism. On the other hand, more light is lost in the reflexion than in the passage through a good object-glass, and the surface of the mirror needs occasional re-polishing or re-coating. For fuller information see TELESCOPE.

The function of a telescope is to increase the "apparent magnitude" of distant objects; *it* does not increase the "apparent brightness." If we put out of account the loss of light by reflexion at glass surfaces (or by imperfect reflexion at metallic surfaces) and by absorption, and suppose that the magnifying power does not exceed the ratio of the aperture of the object-glass to that of the pupil, under which condition the pupil will be filled with light, we may say that the "apparent brightness" is absolutely unchanged by the use of a telescope. In this statement, however, two reservations must be admitted. If the object under examination, like a fixed star, have no sensible apparent magnitude, the conception of "apparent brightness" is altogether inapplicable, and we are concerned only with the total quantity of light reaching the eye. Again, it is found that the visibility of an object seen against a black background depends not only upon the "apparent brightness" but also upon the apparent magnitude. If two or three crosses of different sizes be cut out of the same piece of white paper, and be erected against a black background on the further side of a nearly dark room, the smaller ones become invisible in a light still sufficient to show the larger. Under these circumstances a suitable telescope may of course bring also the smaller objects into view. The explanation is probably to be sought in imperfect action of the lens of the eye when the pupil is dilated to the utmost. The author of this article has found that in a nearly dark room he becomes distinctly short-sighted, a defect of which there is no trace whatever in a moderate light.[1] If this view be correct, the brightness of the image on the retina is really less in the case of a small than in the case of a large object, although the so-called apparent brightnesses may be the same. However this may be, the utility of a night-glass is beyond dispute.

The general law that (apart from the accidental losses mentioned above) the "apparent brightness" depends only upon the area of the pupil filled with light, though often ill understood, has been established for a long time, as the following quotation from Smith's *Optics* (Cambridge, 1738), p. 113, will show.

"Since the magnitude of the pupil is subject to be varied by various degrees of light, let NO be its semi-diameter when the object PL is viewed by the naked eye from the distance OP; and upon a plane that touches the eye at O, let OK be the semi-diameter of the greatest area, visible through all the glasses to another eye at P, to be found as PL was; or, which is the same thing, let OK be the semi-diameter of the greatest area inlightened by a pencil of rays flowing from P through all the glasses; and when this area is not less than the area of the pupil, the point P will appear just as bright through all the glasses as it would do if they were removed: but if the inlightened area be less than the area of the pupil, the point P will appear less bright through the glasses than if they were removed in the same proportion as the inlightened area is less than the pupil. And these proportions of apparent brightness would be accurate if all the incident rays were transmitted through the glasses to the eye, or if only an insensible part of them were stopt."

Resolving Power of Optical Instruments.—According to the principles of common optics, there is no limit to the resolving power of an instrument. If the aberrations of a microscope were perfectly compensated it might reveal to us worlds within a space of a millionth of an inch. In like manner a telescope might resolve double stars of any degree of closeness. The magnifying power may be exalted at pleasure by increase of focal length and of the power of eye-pieces; and there are at any rate some objects, such as the sun, in dealing with which the accompanying loss of light would be an advantage rather than the contrary. How is it, then, that the power of the microscope is subject to an absolute limit, and that if we wish to observe minute detail on the over-lighted disk of the sun we must employ a telescope of large aperture? The answer requires us to go behind the approximate doctrine of rays, on which common optics is built, and to take into consideration the finite character of the wave-length of light.

A calculation based upon the principles of the wave-theory shows that, no matter how perfect an object-glass may be, the image of a star is represented, not by a mathematical point, but by a disk of finite size surrounded by a system of alternately dark and bright rings. Airy found that if the angular radius of the central disk (as seen from the centre of the object-glass) be θ, 2R the aperture, λ the wave-length, then

$$\theta = 1 \cdot 2197 \frac{\lambda}{2R},$$

showing that the definition, as thus limited by the finiteness of λ, increases with the aperture.

In estimating theoretically the resolving power of a telescope on a double star we have to consider the illumination of the field due to the superposition of the two independent images. If the angular interval between the components of the double star were equal to 2θ, the central

[1] *Camb. Phil. Proc.*, vol. iv.

disks would be just in contact. Under these conditions there can be no doubt that the star would appear to be fairly resolved, since the brightness of the external ring systems is too small to produce any material confusion, unless indeed the components are of very unequal magnitude. The diminution of star disks with increasing aperture was observed by W. Herschel; and in 1823 Fraunhofer formulated the law of inverse proportionality. In investigations extending over a long series of years, the advantage of a large aperture in separating the components of close double stars was fully examined by Dawes.

The resolving power of telescopes was investigated also by Foucault, who employed a scale of equal bright and dark alternate parts; it was found to be proportional to the aperture and independent of the focal length. In telescopes of the best construction the performance is not sensibly prejudiced by outstanding aberration, and the limit imposed by the finiteness of the waves of light is practically reached. Verdet has compared Foucault's results with theory, and has drawn the conclusion that the radius of the visible part of the image of a luminous point was nearly equal to half the radius of the first dark ring.

The theory of resolving power is rather simpler when the aperture is rectangular instead of circular, and when the subject of examination consists of two or more light or dark lines parallel to one of the sides of the aperture. Supposing this side to be vertical, we may say that the definition, or resolving power, is *independent of the vertical aperture*, and that a double line will be about on the point of resolution when its components subtend an angle equal to that subtended by the wave-length of light at a distance equal to the *horizontal aperture.*

The resolving power of a telescope with a circular or rectangular aperture is easily investigated experimentally. The best object is a grating of fine wires, about fifty to the inch, backed by a soda-flame. The object-glass is provided with diaphragms pierced with round holes or slits. One of these, of width equal, say, to one-tenth of an inch, is inserted in front of the object-glass, and the telescope, carefully focused all the while, is drawn gradually back from the grating until the lines are no longer seen. From a measurement of the maximum distance the least angle between consecutive lines consistent with resolution may be deduced, and a comparison made with the rule stated above.

Merely to show the dependence of resolving power on aperture it is not necessary to use a telescope at all. It is sufficient to look at wire-gauze backed by the sky, or by a flame, through a piece of blackened cardboard pierced by a needle and held close to the eye. By varying the distance the point is easily found at which resolution ceases; and the observation is as sharp as with a telescope. The function of the telescope is in fact to allow the use of a wider, and therefore more easily measurable, aperture. An interesting modification of the experiment may be made by using light of various wave-lengths.

In the case of the microscope the wave-theory shows that there must be an absolute limit to resolving power independent of the construction of the instrument. No optical contrivances can decide whether light comes from one point or from another if the distance between them do not exceed a small fraction of the wave-length. This idea, which appears to have been familiar to Fraunhofer, has recently been expanded by Abbe and Helmholtz into a systematic theory of the microscopic limit. See MICROSCOPE.

Similar principles may be applied to investigate the resolving power of spectroscopes, whether dispersing or diffracting. Consider for simplicity any combination of prisms, anyhow disposed, but consisting of one kind of glass. Let a be the final width and μ the index of a parallel beam passing through, and let the thicknesses of glass traversed by the extreme rays on either side be t_2 and t_1. It is not difficult to see that, if the index be changed to $\mu+\delta\mu$, the rays will be turned through an angle θ given by

$$\theta=\frac{\delta\mu(t_2-t_1)}{a}.$$

Now, if the two kinds of light correspond to a double line which the instrument can just resolve, we have $\theta=\lambda/a$, and thus

$$t_2-t_1=\lambda/\delta\mu,$$

a formula of capital importance in the theory of the dispersing spectroscope. In a well-constructed instrument, t_1, the smaller thickness traversed, may be small or negligible, and then we may state the law in the following form:—the smallest thickness of prisms necessary for the resolution of a double line whose indices are μ and $\mu+\delta\mu$ is found by dividing the wave-length by $\delta\mu$.

As an example, let it be required to find the smallest thickness of a prism of Chance's "extra dense flint," necessary for resolution of the soda-lines.

By Cauchy's formula for the relation between μ and λ we have

$$\mu=A+B\lambda^{-2}, \qquad \delta\mu=-2B\lambda^{-3}\delta\lambda.$$

From the results given by Hopkinson for this kind of glass we find

$$B=\cdot984\times10^{-10},$$

the unit of length being the centimetre. For the two soda-lines

$$\lambda=5\cdot889\times10^{-5}, \qquad \delta\lambda=\cdot006\times10^{-5};$$

and thus the thickness t necessary to resolve the lines is

$$t=\frac{\lambda^4}{2B\delta\lambda}=\frac{10^{10}\lambda^4}{1\cdot968\delta\lambda}=1\cdot02 \text{ centimetre},$$

the meaning of which is that the soda-lines will be resolved if, and will not be resolved unless, the difference of thicknesses of glass traversed by the two sides of the beam amount to one centimetre. In the most favourable arrangement the centimetre is the length of the base of the prism. It is to be understood, of course, that the magnifying power applied is sufficient to narrow the beam ultimately to the diameter of the pupil of the eye; otherwise the full width would not be utilized.

The theory of the resolving power of a diffracting spectroscope, or grating, is even simpler. Whatever may be the position of the grating, a double line of wave-lengths λ and $\lambda+\delta\lambda$ will be just resolved provided

$$\frac{\delta\lambda}{\lambda}=\frac{1}{mn},$$

where n is the total number of lines in the grating, and m is the order of the spectrum under examination.

If a grating giving a spectrum of the first order and a prism of extra dense glass have equal power in the region of the soda-lines, the former must have about as many thousand lines as the latter has centimetres of available thickness.

The dispersion produced by a grating situated in a given manner is readily inferred from the resolving power. If a be the width of the beam after leaving the grating, the angle $\delta\theta$, corresponding to the limit of resolution, is λ/a, and thus

$$\frac{\delta\theta}{\delta\lambda}=\frac{mn}{a}.$$

Thus the dispersion depends only upon the order of the spectrum, the total number of lines, and the width of the emergent beam.

An obvious inference from the necessary imperfection of optical images is the uselessness of attempting anything like an absolute destruction of aberration. In an instrument free from aberration the waves arrive at the focal point in the same phase. It will suffice for practical purposes if the error of phase nowhere exceeds $\frac{1}{4}\lambda$. This corresponds to an error of $\frac{1}{8}\lambda$ in a reflecting and $\frac{1}{2}\lambda$ in a (glass) refracting surface, the incidence in both cases being perpendicular.

If we inquire what is the greatest admissible longitudinal aberration in an object-glass according to the above rule, we find

$$\delta f=\lambda\alpha^{-2},$$

α being the angular semi-aperture.

In the case of a single lens of glass with the most favourable curvatures, δf is about equal to $f\alpha^2$; so that α^4 must not exceed λ/f. For a lens of 3-feet focus this condition is satisfied if the aperture do not exceed 2 inches.

When parallel rays fall directly upon a spherical mirror the longitudinal aberration is only about one-eighth as great as for the most favourable-shaped single lens of equal focal length and aperture. Hence a spherical mirror of 3-feet focus might have an aperture of $2\frac{1}{2}$ inches, and the image would not suffer materially from aberration.

For fuller information on the subject of the preceding paragraphs see Lord Rayleigh's papers entitled "Investigations in Optics," *Phil. Mag.*, 1879, 1880. On general optics the treatises most accessible to the English reader are Parkinson's *Optics* (3d ed., 1870) and Glazebrook's *Physical Optics* (1883). Verdet's *Leçons d'optique physique* is an excellent work. Every student should read the earlier parts of Newton's Optics, in which are described the fundamental experiments upon the decomposition of white light. (R.)

OPTIMISM. See PESSIMISM.

ORACLE. It was a universal belief in the ancient world that there is a capacity in the human mind to divine the will of God (μαντικόν τι ἡ ψυχή, Plato, *Phædr.*, 242 C). This capacity is not equally developed in all men, and, practically, a very few persons, in whom it is strong, are distinguished from the mass as μάντεις. These are able to understand the methods by which the gods reveal their intentions to men. There occur cases where the gods speak directly to men, where a divine voice is heard issuing its commands or warnings, but these instances are confined, except in a few remarkable historical cases (such as the appearance of Pan to the Athenian messenger, 490 B.C., Herod., vi. 105), to the heroic age and to epic poetry. Setting these aside, we find that the divine will was revealed to the interpreting medium in two ways—by inspiration and by signs. In the former case the divine influence overpowers the soul of the medium and takes entire possession of it for the time. The medium cannot himself bring on a revelation, but is at rare intervals affected by the power of the god, his consciousness ceases, and the god speaks through him words which he is himself unable to control or even to understand. So, for example, the *prophetes* of Apollo Ptoios gave a response in the Carian language, which no one except the questioner could understand (Herod., viii. 135). The second method of revelation, by signs, required a distinct art of interpretation; certain events, phenomena in the heavens or in bird or animal life, the conduct of sacrificial animals and the appearance presented by their entrails, &c., presaged the will of the god to him who possessed the art of interpreting them. The second method was called *artificial* (ἔντεχνος), in opposition to the first, which is direct and *artless* (ἄτεχνος).

In every case the revelation of the divine will is dependent on the direct act of the god; he affects the soul of the μάντις when and where he pleases; he sends, when he chooses, the signs from which his intentions can be inferred. There was, however, a belief that at certain places the god gave revelations more frequently than at others. Such places were generally characterized by some marked physical feature. At these places there were established regular institutions, with a staff of priests and prophets, to which the neighbours resorted for counsel; the Latin term "oracle" (in Greek μαντεῖα, χρηστήρια) is the general name. With regard to these institutions we have to consider (1) their method of interpretation, in so far as this is not most naturally given under the articles treating of the particular localities, and (2) their rank and influence among the Greeks.

1. The methods of interpretation varied greatly. Even at the same oracle several methods were often practised side by side. In the most primitive the spirits of the dead appeared and conversed directly with the inquirer. This method was rare in Greece; but an undoubtedly good example is recorded (Herod., v. 92) in Thesprotia, where Periander sent to consult the shade of his wife Melissa; a Biblical instance is the apparition of the shade of Samuel to Saul. The visit of Odysseus to the lower world is obviously a mere poetical version of the consultation of a Bœotian oracle of Tiresias, where the hero spoke directly to his devotees. In the oracle of Trophonius at Lebadea in Bœotia the method of inquiry was certainly modelled after the idea of a descent to the infernal world. Beside the oracle were the two springs of Memory and Oblivion, which, according to the mystic teaching, were the two fountains of the lower world. The inquirer descended into an underground place, and, it is said, saw such sights that he never smiled again. This method belonged to a very primitive stage of Greek history; and it is certain that Greek religion in general, and many oracles in particular, had experienced a long development before the time which we know best. Probably this method was originally more widely practised than we can actually trace.

The common method of revelation in hero-oracles, and in the oracles of some gods, was through dreams. Hero-oracles were certainly in their earliest form simply oracles of the dead; the word ἥρως is a generic term for a dead man. We can trace occasional survivals of the most primitive form of the hero-oracle. The person who seeks advice goes to sleep over the actual grave, and the dead man appears in a dream. A type of the usual method, which was called "incubation" or ἐγκοίμησις, is the oracle of Amphiaraus near Oropus, beside the spring where the hero had risen from the earth to become a god. The inquirer, after abstaining from wine for three days and from all food for twenty-four hours, slept in the temple on the skin of a ram which he had sacrificed. The oracles of Gæa or Ge are closely connected with those of the dead and of heroes. The Earth is giver of responses, as being the home of the dead, who sleep in her womb, but who can be called forth to give counsel to their descendants living on earth. Earth-oracles also belong to a primitive stage of Hellenic religion, and had in historical times either given place to oracles of more developed Hellenic type or occupied a very secondary position. In Olympia it is probable that the oracle of Gæa was the oldest institution, and it is universally recognized in ancient and modern times that the Delphic oracle originally belonged to the same goddess. Probably the cleft in the earth in the Delphic adyton was originally conceived as the passage of communication between the dead under the earth and the living on its surface. A uniform tradition (Paus., x. 5, 3; Æsch., *Cho.*, 1 *sq.*) recognizes one most important fact: in the progress of Greek history, as religious thought developed, there was a progressive development in the character of the Delphic oracle. Gæa was replaced by Themis, a more moralized conception of the Earth-goddess, as the incarnation of natural order and law; but Apollo, the highest creation of Hellenic religion, finally occupies Delphi as the prophet and counsellor of his people. The oracles of Apollo work through inspiration. In Delphi the seer was a woman, Pythia, who was thrown into a state of ecstatic frenzy by the influence of a vapour ascending from a cleft in the earth within the adyton, and while in this state uttered words and cries which contained the answer of Apollo. All the methods of interpretation by signs were practised at different oracles in Greece; even in Apolline oracles, such as the Delphic, the artificial method was employed along with that by inspiration.

2. The original purpose of the oracles was not to foretell the future, but to give counsel as to conduct in doubtful and difficult situations. In cases where human prudence and skill seemed to fail, recourse was had to the oracle, and the god gave advice to his people. Now it was the universal practice that the priests should take the answers, usually incoherent and unintelligible, of the seers and reduce them to form, often metrical; practically the oracles were worked by the priests, and it is obvious that their character depended entirely on the character of the priests and of the nation as a whole. The influence of the oracles could be good only so long as the priests were not only honest and of lofty intentions, but also in a more advanced intellectual position than the people. In the early age of Greek history, when there was no education except what was to be gained by wide intercourse, the priests of such an oracle as Delphi occupied a most advantageous position. To Delphi as the γῆς ὄμφαλος, the central point of the civilized world, came embassies from every Greek city, and even from great non-Greek states such as Lydia and Phrygia. It was a knot where every strand in civilized

life was united. In accordance with this we find that almost all the great lawgivers and sages of the 8th and 7th centuries B.C. were in close relation with the Delphic oracle. All questions of colonization were referred to the oracle, and it is due a good deal to this central guiding influence that the overflow of the teeming population of Greece was directed so systematically. It is instructive to compare the position of the oracles in Greece with those of the kindred races of Asia Minor. In the latter country the god is supreme over his people, the government is a pure theocracy, and the priests, as interpreters of the divine will, are absolute masters of the servants of the god. In Greece it is wholly different. In both cases the oracles are the creation of the national genius,—in Asia Minor Oriental and stationary, in Greece living and progressive. In the earliest time we can trace the influence of the oracles discouraging the relentless blood-feud, distinguishing classes of murder, and allowing purification and expiation in suitable cases. They make the sanctity of oaths between man and man a special duty: Apollo regards even hesitation to keep a pledge as already a sin (Herod., vi. 86; *cf.* i. 159). They are the centre of unions or amphictyonies which bind their members to observe certain duties and show mercy to their fellow-members; and Delphi, as the oracle of an amphictyony including great part of Greece, had an important share in promoting that ideal unity of the whole country which, though never realized, yet floated always before the Greek mind. The oracles did something towards uniting the efforts of Greeks against foreigners, and towards spreading Greek influence abroad in a systematic way.

As education became more general the qualification of superior knowledge necessary to the proper working of the oracles was more difficult to keep up. At the same time the growth of political life in the states intensified their mutual enmities, and made it impossible for the oracles to maintain an attitude of perfect justice, neutrality, and superiority. Though the custom continued till a late period in Greek history that each state should consult the oracle in difficulties, yet complaints of partiality become frequent. Concurrently with the degradation in this respect there grew a demoralization in the whole tone of the oracles: they were consulted by all in the most trivial matters. It became an object to the priests to facilitate the access of votaries who contributed to the wealth of the temple. Whereas originally the Delphic oracle spoke only once a year, the number of days on which it was open to inquirers was gradually increased; and other oracles in like manner turned their attention to the wants of every applicant. In Dodona a large number of leaden tablets have been discovered containing the questions addressed to the god by inquirers; they range in date from the end of the 5th century B.C. onwards, and do not give any very high idea of the kind of difficulties in which the god was asked to advise his worshipper.

See Carapanos, *Dodone*, also an important article in Fleckeisen's *Jahrbücher* for 1883. The most complete work on oracles is Bouché Leclerc's *Histoire de la divination dans l'antiquité*. (W. M. RA.)

ORAN (Arabic, *Wahrán*), the chief town of the department and military division which form the western part of the French colony of Algeria, lies at the head of a bay on the Mediterranean, in 35° 44′ N. lat., and almost on the meridian of Greenwich. The population of the town in 1881 was 58,530; that of the commune, including town and suburbs, 59,377. In 1876, when the total for the town, besides 3728 in prisons, hospitals, &c. (5030 in 1881), was 45,640, 11,047 were French, 4948 Jews, 4782 natives, and 24,863 foreigners. The town is cut in two by the ravine of Oued Rekhi, now partly covered over by boulevards and buildings. West of the ravine lies the port, and above this the old Spanish town with the ancient citadel looking down on it. On the east side the modern castle and the modern town (built since the Spanish occupation) rise like an amphitheatre, and here, too, are the Moorish houses of the Jews' quarter. Taken altogether, Oran has the shape of a triangle, the sea forming the base, and the angles at north-west, north-east, and south being respectively the Fort de la Moune, the modern castle, and Fort St André. Ramparts and forts are mainly of Spanish construction; to the east they have been rebuilt since the French occupation in advance of their old position. Of the six gates, three are on the west side, two on the south, and one on the east. The modern castle was formerly the seat of the beys of Oran; it is now occupied by the general in command of the military division, and also serves as barracks, and accommodates most of the military departments. The old castle was the residence of the Mohammedan rulers previous to the Spanish conquest, and continued to be the residence of the governors of the town up to the earthquake of 8th and 9th October 1790. The portion of the building which still remains is used as barracks and a military prison. Immediately behind, the Mourdjadjo hill rises to a height of 1900 feet; on the way up are passed Fort St Grégoire, the votive chapel commemorative of the cholera of 1849, and Fort Santa Cruz, crowning at a height of 1312 feet the summit of the Aidour. Lastly, Fort de la Moune (so called from the monkeys which are said to have haunted the neighbourhood) rises between the sea and the road from Oran to Mers al-Kebir. In the Spanish town the streets are steep, sometimes even becoming stairs; the "places" are mere widenings of the street. In the French town the streets are well laid out and fit for carriages, and there are various public squares, notably the Place d'Armes; the houses too, in spite of the risk from earthquakes, are built in the French style, several stories high. It is only in the Jews' quarter that the houses are of a peculiar type,—one-storied, with white-washed or red-washed walls, and enclosing an inner court shaded by a vine. Oran is the see of a bishopric dependent on the archbishopric of Algiers. The cathedral (St Louis) is an ancient mosque which has successively been a Roman Catholic chapel, a synagogue, and again a Catholic church according as the town changed hands. The last restoration was in 1839. A fine picture representing the landing of St Louis at Tunis deserves to be mentioned. The grand mosque (in Rue Philippe) was erected at the end of last century in commemoration of the expulsion of the Spaniards, and with money paid as ransom for Christian slaves. The minaret is one of the prettiest in Algeria. Other mosques have been utilized for military purposes. Permanent quarters have not yet been assigned to the prefecture, the courts of justice, and other civil offices; the bank alone occupies a building of an imposing character. The military hospital contains 1400 beds. Oran is well supplied with water; and a number of beautiful promenades greatly increase its attractions. The main peculiarity of the streets is the mixture of races, each with its own type and costume. Arabs, Spaniards, and Turks, successive masters of the town, have all left descendants; and with these are mingled black-gabardined Jews, Spanish immigrants of recent date in Andalusian garb, French soldiers of all branches of the service, Moors with nonchalant gait, and negroes, who serve as porters and day-labourers for the community. The negroes occupy a whole village on the outskirts of the town. While industrially of no importance, Oran is admirably situated for commerce. From Cartagena to Oran is the shortest passage between Europe and Algeria, and there is regular communication with Marseilles, Cette, and Port Vendres in France, with Barcelona,

Valencia, Cartagena, Malaga, and Gibraltar in Spain, and with the various ports on the Barbary coast. A railroad (261 miles) runs to Algiers and is joined at Perregaux by the line from Arzeu to Saida and the Kreider, which serves the high halfa (esparto) plateaus. There is also a railway to Sidi Bel-Abbès. Previous to the French occupation there was no port at Oran, vessels anchoring at Mers al-Kebir at the north-west entrance of the bay. Mers al-Kebir is now reserved for the navy, and a harbour of 60 acres has been constructed by means of a pier 3280 feet long from Fort de la Moune, and two cross piers. A geographical society was founded at Oran in 1878.

If Oran was not already occupied in the time of the Romans, its foundation must be ascribed to the Andalusian seamen who settled there in the beginning of the 10th century. Rapidly rising into importance, it was taken and retaken, pillaged and rebuilt, by the various conquerors of northern Africa. Almoravides, Almohades, and Merinides succeeded each other, and in the space of half a century the town changed hands nine times. At length, in the latter half of the 15th century, it was subject to the sultans of Tlemcen, and reached the height of its prosperity. Active commerce was maintained with the Venetians, the Pisans, the Genoese, the Marseillese, and the Catalans, who imported the produce of their looms, glass-wares, tin-wares, and iron, and received in return ivory, ostrich feathers, gold-dust, tanned hides, grain, and negro slaves from the interior of Africa. Admirable woollen cloth and splendid arms were locally manufactured. The magnificence of its mosques and other public buildings, the number of its schools, and the extent of its warehouses shed lustre on the city; but wealth and luxury began to undermine its prosperity, and its ruin was hastened by the piracy to which the Moorish refugees from Spain betook themselves. Animated by the patriotic enthusiasm of Cardinal Ximenes, the Spaniards determined to put a stop to those expeditions which were carrying off their countrymen, destroying their commerce, and even ravaging their country. Mers al-Kebir fell into their hands on 23d October 1505, and Oran in May 1509. The latter victory, obtained with but trifling loss, was stained by the massacre of a third of the Mohammedan population. From 6000 to 8000 prisoners, 60 cannon, engines of war, and a considerable booty from the wealth accumulated by piracy fell into the hands of the conquerors. Cardinal Ximenes introduced the Catholic religion, with its churches, convents, Inquisition, &c., and also restored and extended the fortifications. Oran became the penal settlement of Spain, but neither the convicts nor the noblemen in disgrace who were also banished thither seem to have been under rigorous surveillance; fêtes, games, bull-fights, &c., were held. Meanwhile the Turks had become masters of Algeria, and expelled the Spaniards from all their possessions except Oran. The bey, finally settling at Mascara, watched his opportunity; and at length, in 1708, the weakness of Spain and the treason of the count of Vera Cruz obliged the city to capitulate. The Spaniards recovered possession in 1732, but found the maintenance of the place a burden rather than a benefit, all the neighbouring tribes having ceased to have dealings with the Christians. The earthquake of 1790 furnished an excuse for withdrawing their forces. Commencing by twenty-two separate shocks at brief intervals, the oscillations continued from 8th October to 22d November. Houses and fortifications were overthrown, and a third of the garrison and a great number of the inhabitants perished. Famine and sickness had begun to aggravate the situation when the bey of Mascara appeared before the town with 30,000 men. By prodigies of energy the Spanish commander held out till August 1791, when, having made terms with the dey of Algiers, he was allowed to set sail for Spain with his guns and ammunition. The bey Mohammed took possession of Oran in March 1792, and made it his residence instead of Mascara. On the fall of Algiers the bey placed himself under the protection of the conquerors. The French army entered the town 4th January 1831, and took formal possession on the 17th of August.

ORANG. See APE, vol. ii. p. 149.

ORANGE (*Citrus Aurantium*), the plant that produces the familiar fruit of commerce, is closely allied to the citron, lemon, and lime, all the cultivated forms of the genus *Citrus* being so nearly related that their specific demarcation must be regarded as somewhat doubtful and indefinite. Risso and Poiteau have described eighty kinds of orange (including the bergamots), chiefly differing in the external shape, size, and flavour of the fruit; but all may probably be traced to two well-marked varieties—the Sweet or China Orange and the Bitter Orange or Bigarade,—though several of these modifications seem to indicate crossing with the lemon or citron, if, indeed, they do not rather point to a more remote common origin from a primitive citrine type.

The bitter orange, by some made a sub-species (*C. vulgaris*), is a rather small tree, rarely exceeding 30 feet in height. The green shoots are furnished with sharp axillary spines, and alternate evergreen oblong leaves, pointed at the extremity, and with the margins entire or very slightly serrated; they are of a bright glossy green tint, the stalks

Orange (*Citrus Aurantium*), from nature, about one-third natural size. *a*, diagram of fruit, after Luerssen, *Med.-Pharm. Botanik*, 1882.

distinctly winged and, as in the other species, articulated with the leaf. The fragrant white or pale pinkish flowers appear in the summer months, and the fruit, usually round or spheroidal, does not perfectly ripen until the following spring, so that flowers and both green and mature fruit are often found on the plant at the same time. The bitter aromatic rind of the bigarade is rough, and dotted closely over with concave oil-cells; the pulp is acid and more or less bitter in flavour. The sweet orange generally has the shoots destitute of spines, the petioles less distinctly winged, and the leaves more ovate in shape, but chiefly differs in the fruit, the pulp of which is agreeably acidulous and sweet, the rind comparatively smooth, and the oil-cells convex. The ordinary round shape of the sweet orange fruit is varied greatly in certain varieties, in some being greatly elongated, in others much flattened; while several kinds have a conical protuberance at the apex, others are deeply ribbed or furrowed, and a few are distinctly "horned" or lobed, by the partial separation of the carpels. The two sub-species of orange are said by some authorities to reproduce themselves infallibly by seed; and, where hybridizing is prevented, the seedlings of the sweet and bitter orange appear to retain respectively the more distinctive features of the parent plant; but where growing wild for successive generations they show a tendency to degenerate, the progeny of the sweet orange being apt to assume the broadly-winged petioles and spiny shoots of the bigarade.

Though now cultivated widely in most of the warmer parts of the world, and apparently in many completely naturalized, the diffusion of the orange has taken place in comparatively recent historical periods. To ancient Mediterranean agriculture it was unknown; and, though the later Greeks and Romans were familiar with the citron as an exotic fruit, their "Median Apple" appears to have been the only form of the citrine genus with which they were acquainted. The careful researches of Gallesio have

proved that India was the country from which the orange spread to western Asia and eventually to Europe. Oranges are at present found wild in the jungles along the lower mountain slopes of Sylhet, Kumaon, Sikkim, and other parts of northern India, and, according to Royle, even in the Neilgiri Hills; the plants are generally thorny, and present the other characters of the bitter variety, but occasionally wild oranges occur with sweet fruit; it is, however, doubtful whether either subspecies is really indigenous to Hindustan, and De Candolle is probably correct in regarding the Burmese peninsula and southern China as the original home of the orange. Cultivated from a remote period in Hindustan, it was carried to south-western Asia by the Arabs, probably before the 9th century, towards the close of which the bitter orange seems to have been well known to that people; though, according to Mas'ûdi, it was not cultivated in Arabia itself until the beginning of the 10th century, when it was first planted in 'Omán, and afterwards carried to Mesopotamia and Syria. It spread ultimately, through the agency of the same race, to Africa and Spain, and perhaps to Sicily, following everywhere the tide of Mohammedan conquest and civilization. In the 12th century the bigarade was abundantly cultivated in all the Levant countries, and the returning soldiers of the Cross brought it from Palestine to Italy and Provence. An orange tree of this variety is said to have been planted by St Dominic in the year 1200, though the identity of the one still standing in the garden of the monastery of St Sabina at Rome, and now attributed to the energetic friar, may be somewhat doubtful. No allusion to the sweet orange occurs in contemporary literature at this early date, and its introduction to Europe took place at a considerably later period, though the exact time is unknown. It was commonly cultivated in Italy early in the 16th century, and seems to have been known there previously to the expedition of Da Gama (1497), as a Florentine narrator of that voyage appears to have been familiar with the fruit. The importation of this tree into Europe, though often attributed to the Portuguese, is with more probability referred to the enterprise of the Genoese merchants of the 15th century, who must have found it growing abundantly then in the Levant. The prevailing European name of the orange is sufficient evidence of its origin and of the line taken in its migration westward. The Sanskrit designation *nagrunga*, becoming *narunger* in Hindustani, and corrupted by the Arabs into *nâranj* (Spanish *naranja*), passed by easy transitions into the Italian *arancia* (Latinized *aurantium*), the Romance *arangi*, and the later Provençal *orange*. The true Chinese variety, however, was undoubtedly brought by the Portuguese navigators direct from the East both to their own country and to the Azores, where now luxuriant groves of the golden-fruited tree give a modern realization to the old myth of the gardens of the Hesperides.[1] Throughout China and in Japan the orange has been grown from very ancient times, and it was found diffused widely when the Indian Archipelago was first visited by Europeans. In more recent days its cultivation has extended over most of the warmer regions of the globe, the tree growing freely and producing fruit abundantly wherever heat is sufficient and enough moisture can be supplied to the roots; where night-frosts occur in winter or spring the culture becomes more difficult and the crop precarious.

The orange flourishes in any moderately fertile soil, if it is well drained and sufficiently moist; but a rather stiff loam or calcareous marl, intermingled with some vegetable humus, is most favourable to its growth. Grafting or budding on stocks raised from the seed of some vigorous variety is the plan usually adopted by the cultivator. The seeds, carefully selected, are sown in well-prepared ground, and the seedlings removed to a nursery-bed in the fourth or fifth year, and, sometimes after a second transplantation, grafted in the seventh or eighth year with the desired variety. When the grafts have acquired sufficient vigour, the trees are placed in rows in the permanent orangery. Propagation by layers is occasionally adopted; cuttings do not readily root, and multiplication directly by seed is always doubtful in result, though recommended by some authorities. The distance left between the trees in the permanent plantation or grove varies according to the size of the plants and subsequent culture adopted. In France, when the trunks are from 5 to 6½ feet in height, a space of from 16 to 26 feet is left between; but the dwarfer trees admit of much closer planting. In the West Indies and Azores an interval of 24 or even of 30 feet is often allowed. The ground is kept well stirred between the trunks, and the roots manured with well-rotted dung, guano, or other highly nitrogenous matter; shallow pits are sometimes formed above the roots for the reception of liquid or other manures; in dry climates water must be abundantly and frequently supplied. The trees require regular and careful pruning, the heads being trained as nearly as possible to a spherical form. Between the rows melons, pumpkins, and other annual vegetables are frequently raised. In garden culture the orange is often trained as an espalier, and with careful attention yields fruit in great profusion when thus grown. In favourable seasons the oranges are produced in great abundance, from 400 to 1000 being commonly borne on a single plant in full bearing, while on large trees the latter number is often vastly exceeded. The trees will continue to bear abundantly from fifty to eighty years, or even more; and some old orange trees, whose age must be reckoned by centuries, still produce their golden crop; these very ancient trees are, however, generally of the bitter variety. Oranges intended for export to colder climates are gathered long before the deep tint that indicates maturity is attained, the fruit ripening rapidly after picking; but the delicious taste of the mature China orange is never thus acquired, and those who have not eaten the fruit in a perfectly ripe state have little idea of its flavour when in that condition. Carefully gathered, the oranges are packed in boxes, each orange being wrapped in paper, or with dry maize husks or leaves placed between them. The immense quantities of this valuable fruit imported into Britain are derived from various sources, but those kinds in most esteem are the produce of the Azores, whence, in 1878, 410,101 boxes, each holding 400 "St Michael's" oranges, are said to have been sent to Great Britain alone. Large numbers are also exported to England from Sicily, Portugal, and Spain, and a considerable amount from other Mediterranean countries. North America is largely supplied from Jamaica and the Bahamas; but the extensive and rapidly increasing cultivation of the tree in Florida will probably in a few years supersede the foreign importation. In that State the bitter orange has grown, from an unknown period, in a wild condition, and some of the earlier botanical explorers regarded it as an indigenous tree; but it was undoubtedly brought by the Spanish colonists to the West India Islands, and was probably soon afterwards transplanted to Florida by them or their buccaneering enemies. The climate of Florida seems remarkably adapted for orange culture, and orangeries are becoming yearly more numerous and extensive,—the wild stocks, or those raised from wild seed, being generally employed by the grafter. In the other Gulf States this branch of agricultural industry is pursued to some extent; and in California the orange groves are productive and increasing.

[1] The modern Arabic name, Bortukân (that is, Portuguese), shows that the China apple reached the Levant from the West.

Orange cultivation has been attempted with success in several parts of Australia, especially in New South Wales, where the orange groves near Paramatta yield an abundant colonial supply. The orangeries of Queensland and South Australia are likewise producing well, though, as yet, Australian fruit is chiefly consumed at home. In many of the Pacific Islands the plant has been long established: Tahiti exports oranges largely to San Francisco, and in Fiji the culture promises to become of considerable importance.

Certain varieties of orange deserve mention, from the peculiar character of their fruit. The Mandarin orange of China, sometimes made a distinct species, *C. nobilis*, is remarkable for its very flat spheroidal fruit, the rind of which readily separates with the slightest pressure; the pulp has a peculiarly luscious flavour when ripe. The small Tangerine oranges, valued for their fine fragrance, are derived from the Mandarin. "Maltese" or "Blood" oranges, much grown in southern Italy, are distinguished by the deep-red tint of the pulp. The Bergamot has been already described (see vol. iii. p. 587). Orange plantations in Europe suffer much at times from a disease called by the French *charbon*, caused by a fungus (*Dematium monophyllum*), which rapidly spreads over stems, leaves, and green fruit. Several insect enemies attack the plant, of which the scale-like *Coccus citri* is the most injurious in Europe; in the Azores *C. Hesperidis* takes its place. Cold weather in winter has sometimes proved destructive in Provence, and many plantations were destroyed by the hard frosts of 1789 and 1820.

Besides the widespread use of the fruit as an agreeable and wholesome article of diet, that of the sweet orange, abounding in citric acid, possesses in a high degree the antiscorbutic properties that render the lemon and lime so valuable in medicine; and the free consumption of this fruit in the large towns of England during the winter months has doubtless a very beneficial effect on the health of the people. The juice is sometimes employed as a cooling drink in fevers, as well as for making a pleasant beverage in hot weather; it is likewise an essential ingredient in "orange wine."

The bitter orange is chiefly cultivated for the aromatic and tonic qualities of the rind, which render it a valuable stomachic. Planted long ago in Andalusia by the Moorish conquerors, it is still extensively grown in southern Spain,—deriving its common English name of "Seville" orange from the abundant groves that still exist around that city, though the plant is now largely cultivated elsewhere. The fruit is imported into Great Britain and the United States in considerable quantities for the manufacture of the favourite confection known as orange marmalade, which is prepared from the pulp and rind, usually more or less mingled with the pulp of the China orange. In medicine the dried peel is largely employed as an aromatic tonic, and often, in tincture and infusion, as a mere vehicle to disguise the flavour of more nauseous remedies. The essential oil of the rind is collected for the use of the perfumer, being obtained either by the pressure of the fresh peel against a piece of sponge, or by the process known as *écuelle*, in which the skin of the ripe fruit is scraped against a series of points or ridges arranged upon the surface of a peculiarly-shaped dish or broad funnel, when the oil flows freely from the broken cells. Another fragrant oil, called in France *essence de petit grain*, is procured by the distillation of the leaves, from which also an aromatic water is —, the oscu...rs of both sweet and bitter orange yield, when November. Houses and "oil of Neroli" of the druggist and perof the garrison and a gre fragrant liquid known as "orange-flower Famine and sickness had candied peel is much in request by cook and conthe bey of Me fectioner; the favourite liqueur sold as "curaçoa" derives its By aromatic flavour from the rind of the bigarade. For details of orange varieties, cultivation, &c., see Risso and Poiteau, *Histoire et culture des Orangers* (edited by A. Du Breuil, Paris, 1872); for early history and diffusion, G. Gallesio, *Traité du Citrus*, Paris, 1811. (C. P. J.)

ORANGE, a city of France, the chief town of an arrondissement in the department of Vaucluse, is situated 18 miles north of Avignon on the railway from Lyons to Marseilles at some distance from the left bank of the Rhone, in the midst of meadows, orchards, and mulberry plantations, watered by a stream called the Meyne, and overlooked by the majestic summit of Mount Ventose, which lies 22 miles to the east. The district is highly fertile, and the city deals largely in silks, woollens, and fruits, and also till quite recently in wines and madder. The population of the city numbers 6860. Orange is interesting mainly from its Roman remains. The triumphal arch is not only far finer than any other in France, but ranks third in size and importance among those still extant in Europe. Measuring 72 feet in height, 69 feet in width, and 26 feet in depth, it is composed of three arches supported by four Corinthian columns. On three sides it is well preserved, and displays remarkable variety and elegance in its sculptured decorations. To judge from a partly decipherable inscription, the arch seems to have been erected in the reign of Tiberius. It suffered from being used as a fortification in the Middle Ages. Another most imposing structure is the theatre, built against the hill commanding the town. The façade, which is 118 feet high, 340 feet long, and 13 feet thick, is pierced by three square gates surmounted by a range of blind arches and a double row of far-projecting corbels. Of the seats occupied by the spectators—to the number, it might be, of 7000—only the lower ranges remain. By many this theatre is regarded as the most beautiful, or at least the most imposing, of the Roman monuments of France. The princes of Orange made it an outwork of the castle which they erected on the hill, and which was demolished by De Grignan after he had taken the town for Louis XIV. Up to the beginning of the present century it was filled with hovels and stables; these are now quite swept away, and the preservation of the building assured. In the neighbourhood of the theatre traces have been found of a hippodrome capable of containing 20,000 persons; and statues, bas-reliefs, and ruins of an aqueduct also serve to show the importance of the Roman town. Several of the churches at Orange are very old. Notre Dame, the old cathedral, originally erected by the prefect of Gaul, was ruined by the Barbarians, rebuilt in the 11th century, and damaged by the Protestants. A statue of Rambaud II. count of Orange and that of Gasparin the celebrated agriculturist may also be mentioned.

Orange (*Arausio*), capital of the Cavari, became after Cæsar an important Roman colony. Its ramparts and fine buildings were partly destroyed by the Alemanni and Visigoths, and partly ruined by the erections of the Middle Ages. Orange was included in the kingdom of Austrasia, fell into the hands of the Saracens, and was recovered by Charlemagne. It became an independent countship in the 11th century; and Count Bertrand de Baux (d. 1181) received from Frederick I. the title of prince of Orange. On the death of Philibert of Châlons in 1530 the inheritance fell to his sister's son, René (Renatus) of Nassau Dillenburg, stadholder of the Netherlands, who, dying childless, chose (1544) as his successor his cousin William, afterwards William I. Though Francis I., king of France, whose predecessors had long claimed to be suzerains of the principality, caused it to be declared part of the domain of Provence, Henry II. recognized William's rights in the treaty of Cateau Cambresis, and "prince of Orange" remained the title of the stadholders from Maurice to William III. In 1672 Louis XIV. seized the principality and handed it over to the count of Auvergne in compensation for his loss of the marquisate of Bergen-op-Zoom confiscated by William; but the claims of the house of Nassau were acknowledged by the peace of Ryswick. On William's death there were two claimants, John William Friso of Nassau-Dietz, designated heir by William's will, and Frederick I. king of Prussia, who

held it, as he was next of kin and had been appointed by the will of Frederick Henry. Thereupon Louis XIV. declared the principality forfeited to the French crown and bestowed it on the prince of Conti, who also had pretensions. The parlement of Paris decided that this prince should have the devolutive title; and the territory was confirmed by the treaty of Utrecht, which, however, left the title and coat of arms to the King of Prussia, who still styled himself prince of Orange (Prinz von Oranien). John William Friso, however, assumed the title, and his descendants, the stadtholders and kings of the Netherlands, have all been designated princes of Orange-Nassau.

ORANGE, a city of the United States, in Essex county, New Jersey, 16 miles west of New York by two lines of railway, and connected by tramway with Newark, 3½ miles distant. Beautifully situated on rolling ground about 190 feet above the sea, Orange has become a favourite place of residence for New York business men. To the west lies Llewellyn Park, an area of 750 acres, studded with villas and held in common; and the summit of Orange Mountain (650 feet), a little farther west, is also occupied with villas. Hat making is largely carried on in the city. The population was 9348 in 1870 and 13,207 in 1880. In 1860 the township of Orange received a city charter; and in 1872 the town, diminished by East Orange and part of South and West Orange, was raised to the rank of a city.

ORANGEMEN, an association of Irish Protestants, originating and chiefly flourishing in Ulster, but with ramifications in other parts of the United Kingdom, and in the British colonies. Orangemen derive their name from William III., but neglect the example of that tolerant prince. They are organized in lodges, and it is said that the initiated know each other by secret signs. Much may be learned from their toasts, about which there is no concealment. The commonest form is "the glorious, pious, and immortal memory of the great and good King William, who saved us from popery, slavery, knavery, brass money, and wooden shoes," with profane or truculent additions according to the orator's taste. The brass money refers to James II.'s coinage, and the wooden shoes to his French allies. The final words are often "a fig for the bishop of Cork," in allusion to Dr Peter Browne, who, in 1715, wrote strongly against the practice of toasting the dead. Orangemen are fond of beating drums and flaunting flags with the legend "no surrender," in allusion to Londonderry.

Orangeism is essentially political, and may be useful in so far as it reminds Irish Protestants of their origin and of their common rights under the British crown. But its original object was the maintenance of Protestant ascendency, and too much of its spirit still survives. By repeating irritating watchwords, and publicly keeping anniversaries painful to their neighbours, Orangemen have done much to inflame sectarian animosity; if their celebrations were private, little could be said against them. The first regular lodges were founded in 1795, but the system existed earlier. The Brunswick clubs, founded to oppose Catholic emancipation, were sprigs from the original Orange tree. The orange flowers of the *Lilium bulbiferum* are worn in Ulster on the 1st and 12th July, the anniversaries of the Boyne and Aughrim. Another great day is the 5th of November, when William III. landed in Torbay.

ORANGE RIVER FREE STATE, an independent republic adjoining the Cape Colony, South Africa (see vol. v., Plate I.), is bounded on the N. by the Vaal river, S. by the Orange river, E. by the Caledon river and Drakensberg mountains, and W. by a line dividing it from Kimberley and the diamond fields of Griqualand West. The area is 70,000 square miles, and the population in 1880 was 133,518. Of this total 61,022 were whites or of European extraction (mostly Dutch), and 72,496 coloured or of native races.

The country, which has an average elevation of 4500 feet above the sea, consists of a series of extensive undulating plains, bounded or diversified by detached rocky hills. These plains slope from the central watershed northward and southward respectively to the Vaal and Orange rivers, and are intersected at various intervals by the Wilge, Rhenoster, Valsch, Vet, Modder, and Riet rivers, emptying their waters into the Vaal river, and by the Caledon, which joins the Orange river. The southern and eastern districts are covered with luxuriant grasses, affording excellent pasturage for stock. In the western districts the grasses are gradually being supplanted by a dwarf bush vegetation. The river-banks are fringed with willow, mimosa, and other indigenous trees, and shrubs and trees of larger growth are found on the eastern mountain ranges; but generally the country is woodless, and to remedy this Government offers premiums for the encouragement of tree planting. The geological characteristics are similar to those of the inland districts of Cape Colony. The south-western portion is an extension of the Karoo or lacustrine formation of South Africa, consisting of sandstone and shales intersected by intrusive igneous rocks. In this formation occurs the diamond mine of Jagersfontein, near the village of Fauresmith, which has been worked for several years past. The north-eastern part, again, consists of sandstones and carbonaceous shales resting conformably on the Karoo formation, and containing horizontal coal-seams, classed as of the Triassic period. The coal outcrops in the Kroonstad and Heilbron districts are being utilized. In the Drift deposits along some river-beds, such as the Sand, Caledon, and Vaal rivers, there are accumulations of pebbles, consisting of agate, jasper, chalcedony, carnelian, white quartz, garnets, and occasionally diamonds.

The climate is salubrious, and specially remarkable for its dryness. Thousands of wild game formerly occupied the plains of the state, but their numbers and variety have of late greatly diminished, and some have been entirely exterminated. The lion, giraffe, elephant, and rhinoceros are no longer found. But in a few districts there may still be seen considerable herds of antelopes, such as the springbok, blesbok, and wildebeeste or gnu. The resources of the state are agricultural, pastoral, and mineral. The principal occupations of the inhabitants are the breeding of cattle, horses, goats, merino sheep, and ostriches. Agriculture is attended to on a larger or smaller scale according to the capabilities of the various farms, and vineyards and orchards are planted on many properties. The staple articles of export, however, are wool, skins, ostrich feathers, and diamonds, all of which are shipped from the seaports of the Cape Colony and Natal.

Bloemfontein, the capital and seat of government, is situated about the centre of the state, in 29° 03' S. lat. and 26° 12' E. long. It is an agreeable town, with a population of about 3000, and has a handsome range of public offices, where the volksraad or assembly of the people meets, a high court (consisting of a chief justice and two puisne judges), a municipal burgher council, two banks, two newspapers, two hotels, clubs, a college, schools, and several churches, including the Dutch Reformed church, the Anglican church with a resident bishop, and Wesleyan, Lutheran, and Roman Catholic churches. The Dutch language is officially used in the volksraad and the courts of justice, but English is spoken by the community generally.

The other towns or villages of the state are Fauresmith, Edenburg, Philippolis, Jacobsdal, Boshof, Winburg, Hoopstad, Kroonstad, Heilbron, Frankfort, Harrismith, Ladybrand, Ficksburg, Bethulie, Bethlehem, Smithfield, Rouxville, and Wepener.

At the commencement of this century the country was inhabited by sections of aboriginal tribes—Bushmen, Korannas, and Bechuanas; and soon afterwards a number of Griquas from the north-west of the Cape Colony came in among them. A chronic state of warfare prevailed between these races. In 1824 numerous farmers from the Colony, seeking pastures for their flocks, crossed the Orange river and settled in the territory. These were followed in 1835-36 by large bodies of Dutch Boer emigrants who

left the Colony in order to be beyond British control. They formed a rude government for themselves, and in attempting to exercise authority came into collision with the Griquas, who claimed protection from the Colony, with which they were allied by treaty. The British governor, Sir P. Maitland, intervened in 1845, assisting the Griquas with troops, and defeating the Boers at Zwart Koppies; and, to prevent further collisions, a resident was appointed. In 1848 Governor Sir H. Smith visited the territory, and came to the conclusion that peace could not be maintained among the mixed elements forming the population without the establishment of a regular government. He therefore issued a proclamation, afterwards confirmed by the crown, annexing the territory to the empire under the name of the Orange River British Sovereignty. Thereupon some of the Boers, under their leader Pretorius, took up arms and expelled the British magistrates; but a military force was brought against them by Sir H. Smith in person, and, after a short but sharp encounter at Boomplaats, the Boers were defeated, and the crown's authority re-established and maintained from that time until towards the close of 1853. During this period many Europeans and colonists of European descent took up their abode in the sovereignty. But disturbances again occurred, arising from long-standing disputes between the native tribes; and, in order to chastise the most powerful of them—the Basutos—for certain acts of outrage, Governor Cathcart in 1852 moved a large military expedition against their chief, Moshesh, and the battle of the Berea was fought, after which the chief, on behalf of the tribe, gave in his submission. After this expedition the British Government resolved to withdraw from the territory. *Sir George Clerk* was deputed as a special commissioner to carry out the abandonment of the country; and, notwithstanding the protests of many inhabitants, he formally handed it over to a body of Boer delegates in terms of a convention entered into on the 23d February 1854. They were released from their allegiance, and permitted to constitute an independent republican community of their own, under the title of the "Orange River Free State." Since that time the government has been in the hands of a president assisted by an executive council, with a volksraad or congress elected by the people, exercising all legislative functions.

In the south-eastern portion of the State, and entirely surrounded by it, is a small independent native territory, of which the principal village is Thaba-Nchu, where 10,000 of the Barolong tribe reside, peaceably ruled by their chief according to their own laws.

ORANIENBAUM, a town of European Russia, with a population of about 4000, lies 100 feet above the sea on the south coast of the Gulf of Finland opposite Cronstadt, and is well known for its imperial palace and as a summer resort for the inhabitants of St Petersburg, from which it is 24 miles distant by rail.

In 1714 Menshikoff, to whom the site was presented by Peter the Great, erected for himself the country seat of Oranienbaum: confiscated, like the rest of his estates, in 1727, it became an imperial residence. In 1743 the empress Elizabeth assigned the place to Peter Theodorovitch, who built there a castle, Peterstadt (now destroyed), for his Holstein soldiers. The rise of the town was fostered by the appointment in 1764 of an official for the reception and entertainment of foreign immigrants entering Russia *via* Cronstadt.

ORATORIO. See MUSIC.

ORCAGNA (*c.* 1316-*c.* 1376[1]), whose full name was ANDREA DI CIONE, called ARCAGNUOLO,[2] was the son of a very able Florentine goldsmith, Maestro Cione, said to have been one of the principal artists who worked on the magnificent silver frontal of the high altar of San Giovanni, the Florentine Baptistery. The result of Orcagna's early training in the use of the precious metals may be traced in the extreme delicacy and refined detail of his principal works in sculpture. He had at least three brothers who all practised some branch of the fine arts: Lionardo or Nardo, the eldest, a painter: Matteo, a sculptor and mosaicist; and Jacopo, also a painter. They were frequently associated with Orcagna in his varied labours.

From the time of Giotto to the end of the 14th century Orcagna stands quite pre-eminent even among the many excellent artists of that time. In sculpture he was a pupil of Andrea Pisano; in painting, though indirectly, he was a disciple of Giotto. Few artists have practised with such success so many branches of the arts. Orcagna was not only a painter and sculptor, but also a worker in mosaic, an architect, and a poet. His importance in the history of Italian art rests not merely on his numerous and beautiful productions, but also on his widespread influence, transmitted to his successors through a large and carefully-trained school of pupils. In style as a painter Orcagna comes midway between Giotto and Fra Angelico: he combined the dramatic force and realistic vigour of the earlier painter with the pure brilliant colour and refined unearthly beauty of Fra Angelico. His large fresco paintings are works of extreme decorative beauty and splendour,—composed with careful reference to their architectural surroundings, arranged for the most part on one plane, without the strong foreshortening or effects of perspective with which the mural paintings of later masters are so often marred.

1. *Orcagna as a Painter.*—His chief works in fresco were at Florence, in the church of S. Maria Novella. He first covered the walls of the retro-choir with scenes from the life of the Virgin. These, unfortunately, were much injured by damp very soon after their completion, and towards the end of the following century were replaced by other frescos of the same subjects by Ghirlandaio, who, according to Vasari, made much use of Orcagna's motives and invention. Orcagna also painted three walls of the Strozzi chapel, at the north-east of the same church, with a grand series of frescos, which still exist, though in a much injured and "restored" state. On the northern end wall is the Last Judgment, painted above and round the window, the light from which makes it difficult to see the picture. In the centre is Christ floating among clouds, surrounded by angels; below are kneeling figures of the Virgin and St John the Baptist, with the twelve apostles. Lower still are patriarchs, prophets, and saints, with the resurrection of the blessed and the lost. The finest composition is that on the west wall, unbroken by any window. It represents paradise, with Christ and the Virgin enthroned in majesty among rows of brilliantly-coloured cherubim and seraphim tinged with rainbow-like rays of light. Below are long lines of the heavenly hierarchy mingled with angel musicians; and lower still a crowd of saints floating on clouds. Many of these figures are of exquisite beauty, especially the few that have escaped restoration. Faces of the most divine tenderness and delicacy occur among the female saints; the two central angels below the throne are figures of wonderful grace in pose and movement; and the whole picture, lighted by a soft luminous atmosphere, seems to glow with an unearthly gladness and peace. Opposite to this is the fresco attributed by Vasari to Orcagna's brother Bernardo, or rather Nardo (*i.e.*, Lionardo); it was completely repainted in 1530, so that nothing but the design remains, full of horror and weird imagination. To some extent the painter has followed Dante's scheme of successive circles.

These paintings were probably executed soon after 1350, and in 1357 Orcagna painted one of his finest panel pictures, as a retable for the altar of the same chapel, where it still remains. In the centre is Christ in majesty between kneeling figures of St Peter and St Thomas Aquinas, attended by angel musicians; on each side are standing figures of three other saints. It is a work of the greatest beauty both in colour and composition; it is painted with extreme miniature-like delicacy, and is on the whole very well preserved. This retable is signed, "Añ. dñi. mccclvii Andreas Cionis de Florentia me pinxit."

[1] The dates of Orcagna's birth and death are not exactly known. According to Vasari, he died in 1389 at the age of sixty; but a document dated 1376 provides a guardian for Tessa and Romola, daughters of Orcagna's widow Francesca (see Bonaini, *Mem. Ined.*, pp. 105-6). Probably, therefore, 1376 was the year of his death; and if Vasari is right about his age his birth would have been in 1316. Milanesi, the best editor of Vasari, is inclined to think that Orcagna died in 1368, when he is known to have been seriously ill.

[2] Of this form, sometimes spelt Orcagnuolo, Orcagna is a corruption.

Another fine altar-piece on panel by Orcagna, dated 1363, is preserved in the Cappella de' Medici near the sacristy of Sta Croce: it represents the four doctors of the Latin church. According to Vasari, Orcagna also painted some very fine frescos in Sta Croce, similar in subjects to those attributed to him in the Campo Santo of Pisa, and full of fine portraits. These do not now exist. In the cathedral of Florence, on one of the northern piers, there hangs a nobly-designed and highly-finished picture on panel by Orcagna, representing S. Zanobio enthroned, trampling under his feet Cruelty and Pride; at the sides are kneeling figures of SS. Eugenius and Crescentius,—the whole very rich in colour. The retable mentioned by Vasari as having been painted for the Florentine church of S. Pietro Maggiore is now in the National Gallery of London. It is a richly decorative composition of the Coronation of the Virgin, between rows of saints, together with nine other subjects painted in miniature. Other paintings on panel by Orcagna were sent by the Pope to Avignon, but cannot now be traced. The frescos also have been destroyed with which, according to Vasari, Orcagna decorated the façade of S. Apollinare and the Cappella de' Cresci in the church of the Servi in Florence.[1]

2. *Orcagna as a Sculptor and Architect.*[2]—In 1355 Orcagna was appointed architect to the chapel of Or San Michele in Florence. This curiously-planned building, with a large upper room over the vaulting of the lower part, had been begun by Taddeo Gaddi as a thank-offering for the cessation of the plague of 1348. It took the place of an earlier oratory designed by Arnolfo del Cambio, and was the gift of the united trade guilds of Florence. As to the building itself, it is impossible to say how much is due to Taddeo Gaddi and how much to Orcagna, but the great marble tabernacle was wholly by Orcagna. This, in its combined splendour of architectural design, sculptured reliefs and statuettes, and mosaic enrichments, is one of the most important and beautiful works of art which even rich Italy possesses. It combines an altar, a shrine, a reredos, and a baldacchino. In general form it is perhaps the purest and most gracefully designed of all specimens of Italian Gothic. It is a tall structure of white marble, with vaulted canopy and richly-decorated gables and pinnacles, reaching almost to the vaulted roof of the chapel. The detail is extremely delicate, and brilliant gem-like colour is given by lavish enrichments of minute patterns in glass mosaic, inlaid in the white marble of the structure. It is put together with the greatest care and precision: Vasari especially notes the fact that the whole was put together without any cement, which might have stained the purity of the marble, all the parts being closely fitted together with bronze dowels. The spire-like summit of the tabernacle is surmounted by a figure of St Michael, and at a lower stage on the roof are statuettes of the apostles. The altar has a relief of Hope between panels with the Marriage of the Virgin and the Annunciation. On the right side, looking east, of the base of the tabernacle are reliefs of the Birth of the Virgin and her Presentation in the Temple; on the left, the Nativity and the Adoration of the Magi; and behind, the Presentation of Christ in the Temple, and the Angel warning the Virgin to escape into Egypt. Above the last two subjects are large reliefs of the Death of the Virgin, surrounded by the apostles, and higher still her Assumption; she stands in a vesica, and is borne by angels to heaven. On the base of the Virgin's tomb is inscribed "Andreas Cionis pictor Florentinvs oratorii archimagister extitit hvjvs mccclix." Orcagna's own portrait is given as one of the apostles. In addition to these richly-composed subject-reliefs the whole work is adorned with many other single figures and heads of prophets, angels, and the Virtues, all executed with wonderful finish and refinement. The shrine, which forms an aumbry in the reredos, contains a miraculous picture of the Madonna. A fine bronze screen, with open geometrical tracery, encloses the whole. No work of sculpture in Italy is more magnificent than this wonderful tabernacle, both in general effect and in the delicate beauty of the reliefs and statuettes with which it is so lavishly enriched. It cost the enormous sum of 96,000 gold florins. Unfortunately it is very badly placed and insufficiently lighted, so that a minute examination of its beauties is a work of difficulty.

No mention is made by Vasari of Orcagna's residence in Orvieto, where he occupied for some time the post of "capo-maestro" to the duomo.[1] He accepted this appointment on 14th June 1358 at the large salary (for that time) of 300 gold florins a year. His brother Matteo was engaged to work under him, receiving 8 florins a month. When Orcagna accepted this appointment at Orvieto he had not yet finished his work at Or San Michele, and so was obliged to make long visits to Florence, which naturally interfered with the satisfactory performance of his work for the Orvietans. The result was that on the 12th of September 1360 Orcagna, having been paid for his work up to that time, resigned the post of "capo-maestro" of the duomo, though he still remained a little longer in Orvieto to finish a large mosaic picture on the west front. When this mosaic (made of glass tesseræ from Venice) was finished in 1362, it was found to be uneven in surface, and not fixed securely into its cement bed. An arbitration was therefore held as to the price Orcagna was to receive for it, and he was awarded 60 gold florins.

Vasari mentions as other architectural works by Orcagna the design for the piers in the nave of the Florentine duomo, a zecca or mint, which appears not to have been carried out, and the Loggia dei Lanzi in the Piazza della Signoria. It is, however, more than doubtful whether Orcagna had any hand in this last building, a very graceful vaulted structure, with three semicircular open arches on the side and one at each end, intended to form a sheltered meeting-place for the Priori during elections and other public transactions. This loggia was ordered by the General Council of Florence in 1356, but was not actually begun till the year 1376, after Orcagna's death. The architects were Benci di Cione (possibly a brother of Orcagna) and Simone di Francesco Talenti, both men of considerable reputation in Florence. The sculptured reliefs of the seven Virtues in the spandrels of the arches of the loggia, also attributed to Orcagna by Vasari, were later still. They were designed by Angelo Gaddi (1383-1386), and were carried out by three or four different sculptors.

Pupils of Orcagna named by Vasari are Bernardo Nello, a Pisan, Tommaso di Marco, a Florentine, and, *chief of all*, *Francesco Traini*, whose grand painting on panel of St Thomas Aquinas enthroned with the arch-heretics at his feet still hangs in the church for which it was painted,—Sta Caterina at Pisa. Orcagna had, in addition to the two daughters mentioned above, a son named Cione, who was a painter of but little eminence. Some sonnets attributed to Orcagna exist in MS. in the Strozzi and Magliabecchian libraries

[1] *The magnificent but much injured frescos* of the Last Judgment, Hell, and the Triumph of Death in the Pisan Campo Santo, described with great minuteness and enthusiasm by Vasari, are attributed by him to Orcagna, but internal evidence seems to show that they are productions of the Sienese school. Crowe and Cavalcaselle attribute them to the two brothers Lorenzetti of Siena, but they have been so injured by wet, the settlement of the wall, and repeated retouchings that it is difficult to come to any clear decision as to their authorship. It appears, however, much more probable that they are the work of Bernardo Daddi.

[2] Orcagna was admitted as a member of the Sculptors' Guild in 1352. His name occurs in the roll as "Andreas Cionis vocatus Arcagnolus, pictor."

ORCHESTRA. See MUSIC, *supra*, p. 98.

ORCHHÁ, or TEHRI, a native state in Bundelkhand, Central India, lies between 24° 26′ and 25° 34′ N. lat., and between 78° 28′ 30″ and 79° 23′ E. long., to the south of the British district of Jhánsí. The area is about 2000 square miles; the population in 1881 was 311,514. A great portion of the area is covered with hill jungle and poor soil, and is thinly peopled. The present capital, Tehri, situated in the south-west corner of the state, is a poor ill-built town, the only good house being the palace of the rájá. Orchhá is the oldest and highest in rank of all the Bundelá principalities, and was the only one not held in subjection by the peshwá. The chief received the title of mahárájá in 1865.

ORCHIDS. The word *Orchis* is used in a special sense to denote a particular genus of the Orchid family (*Orchidaceæ*); very frequently, also, it is employed in a more general way to indicate any member of that large and very interesting group. It will be convenient here to use the word *Orchis* as applying to that particular genus which gives its name to the order or family, and to employ the term "orchid" in the less precise sense.

The flowers of all orchids, though extremely diverse within certain limits, and although superficially very different from those of other monocotyledons, are all formed upon one common plan, which is only a modification of that observable in such flowers as those of the narcissus or snowdrop (*Galanthus*). The conformation of those flowers consists essentially in the presence of a six-parted perianth, the three outer segments of which correspond to a calyx, the three inner ones to a corolla. These segments spring apparently from the top of the ovary,—the real explanation, however, being that the end of the flower-stalk or "thalamus," as it grows, becomes dilated into a sort of cup or tube enclosing and indeed closely adhering to the ovary, so that the latter organ appears to be beneath the perianth instead of above it as in a lily, an appearance which has given origin to the term "inferior ovary." Within the perianth, and springing from its sides, or apparently from the top of the ovary, are six stamens

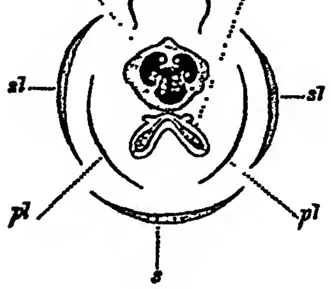

Fig. 1.

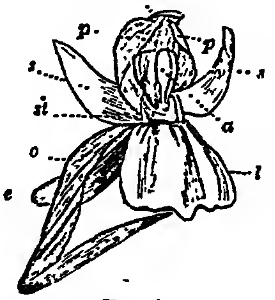

Fig. 2.

FIG. 1.—Diagram of the flower of Orchis. *s, sl, sl*, the three divisions of the outer perianth; *pl, pl*, the two lateral divisions of the inner perianth; *ps*, the superior division or the labellum, which may become inferior by the twisting of the ovary; *e*, the fertile stamen, with its two pollen-masses in the anther-lobes; *c*, the one-celled ovary cut transversely, having three parietal placentas.

FIG. 2.—Flower of an Orchid. *s, s, s*, the three outer divisions of the perianth; *p, p, l*, the three inner, *l* being the labellum, here inferior by the twisting of the ovary; *c*, spur of the labellum; *o*, the twisted ovary; *st*, the stigma; *a*, the anther, containing pollen-masses.

whose anthers contain pulverulent pollen-grains. These stamens encircle a style which is the upward continuation of the ovary, and which shows at its free end traces of the three originally separate but now blended carpels of which the ovary consists. An orchid flower (disregarding for

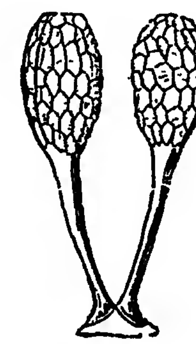

Fig. 4.

FIG. 3.—Upper part of an Orchid flower. The outer divisions of the perianth are seen, and two of the inner, the third or labellum being removed. The two anther lobes are seen with pollen-masses attached to the upper part of the stigma by viscid matter, *re*.

FIG. 4.—Pollen-masses of an Orchid, with their caudicles and common gland.

the moment a very small number of exceptions) has an inferior ovary like that just described, but with the ovules on the walls of the cavity (not in its axis or centre), a six-parted perianth, a stamen or stamens, and a style or styles. The main distinguishing features consist in the fact that one of the inner pieces of the perianth becomes in course of its growth much larger than the rest, and usually different in colour, texture, and form. So different is it that it receives a distinct name, that of the "lip" or "labellum." In place of the six stamens we commonly find but one (two in *Cypripedium*), and that one is inseparably blended with the style to form the "column," bringing about the condition technically called "gynandrous." Moreover, the pollen, instead of consisting of separate cells or grains, consists of cells aggregated into "pollen-masses," the number varying in different genera, but very generally two, four, or eight, and in many of the genera provided at the base with a strap-shaped stalk or "caudicle" ending in a flattish gland or "viscid disk" like a boy's sucker. The style has very generally at its upper part a peculiar pouch-like process called the "rostellum," in which the viscid disk of the pollen-masses is concealed till released in the manner presently to be mentioned. It would appear, then, that the orchid flower differs from the type in the irregularity of the perianth, in the suppression of five out of six stamens and of two out of three styles, and in the union into one column of the one stamen and the one style which remain in the adult flower. In addition to these modifications, which are common to nearly all orchids, there are others generally but not so universally met with; among them is the displacement of the flower arising from the twisting of the inferior ovary, in consequence of which the flower is so completely turned round that the "lip," which originates in that part of the flower, conventionally called the posterior or superior part, or that nearest to the supporting stem, becomes in course of growth turned to the anterior or lower part of the flower nearest to the bract, from whose axil it arises. Other common modifications arise from the union of certain parts of the perianth to each other, and from the inordinate outgrowths from the lip.

These statements are borne out by evidence derived from a variety of sources, such as that afforded by the progressive development of the parts of the flower from their earliest to their most complete condition, by the anatomy or internal organization of the parts of the flower, by the number and distribution of the vascular bundles which run through the cellular tissue, by the comparative morphology of the floral organs of the different genera of the order, and by teratology, or the study of unusual or monstrous forms

tions, which reveals the existence of a complete series of intermediate forms constituting a regular gradation from the ordinary irregular gynandrous flower to regular flowers with six separate stamens such as we have taken as the type.

What brings about—what has brought about—this extraordinary series of changes, by virtue of which a flower typically as regular as a snowdrop becomes transmuted into the forms often more grotesque and extraordinary than can be found in any other group of plants? To the first part of the question the reply is that the present form has been inherited from generation to generation of orchids; to the second part the answer most in accordance with the present state of knowledge is that these modifications are associated with the structure and habits of insects and their visits to the flowers. Cross fertilization, or the impregnation of any given flower by pollen from another flower of the same species on the same or on another plant, has been proved to be of great advantage to the plant by securing a more numerous or a more robust offspring, or one better able to adapt itself to the varying conditions under which it has to live. This cross fertilization is effected by the agency of insects. They are attracted to the flower by its colour or its perfume; they seek, collect, or feed on its honey, and while so doing they remove the pollen from the anther and convey it to another flower, there to germinate on the stigma when its tubes travel down the style and their contents ultimately come in near apposition, perhaps in actual confluence, with the "oosphere" or immature egg, which becomes in consequence fertilized, and thereafter gradually develops into a new plant. To facilitate the operations of such insects, by compelling them to move in certain lines so as to secure the due removal of the pollen and its subsequent deposit on the right place, the form of the flower and the conformation of its several parts are modified in ways as varied as they are wonderful. Other insects visit the flower with more questionable result. For them the pollen is an attraction as food, or some other part of the flower offers an inducement to them for a like object. Such visitors are clearly prejudicial to the flower, and so we meet with arrangements which are calculated to repel the intruders, or at least to force them to enter the flower in such a way as not to effect mischief. It would be quite impossible within the limits of this article to go into detail on this subject. All we can do is to give one or two illustrations, referring the reader desirous of fuller information to Darwin's *Fertilization of Orchids*.

In the common orchids of British meadows, *Orchis Morio*, *mascula* (Shakespeare's long purples), &c., the general structure of the flower is as we have described it. In addition there is in this particular genus, as indeed in many others, a long tubular spur or horn projecting downwards from the back of the lip, whose office it is to secrete and store a honeyed juice; the forepart of the lip forms an expanded plate, usually larger and more brightly coloured than the other parts of the flower, and with hairs or ridges and spots of various kinds according to the species. The remaining parts of the perianth are very much smaller, and commonly are so arranged as to form a hood overarching the "column." This column stands up from the base of the flower, almost at right angles to the lip, and it bears at the top an anther, in the two hollow lobes of which are concealed the two pollen-masses, each with its caudicle terminating below in a roundish gland, concealed at first in the pouch-like rostellum at the front of the column. Below the anther the surface of the column in front is hollowed out into a greenish depression filled with viscid fluid,—this is the stigma. The other parts of the flower need not detain us. Such being in general terms the mechanism of the flower of a common orchis, let us now see how it acts. A bee, we will assume, attracted by the colour and perfume of the flower, alights on that part of it which is the first to attract its attention,—the lip. There, guided by the hairs or ridges before-mentioned, it is led to the orifice of the spur with its store of honeyed juice. The position of this orifice, as we have seen, is at the base of the lip and of the column, so that the insect, if of sufficient size, while bending his head to insert his proboscis into the spur, almost of necessity displaces the pollen-masses. Liberated from the anthers, these adhere to the head or back of the insect by means of the sticky gland at the bottom of the caudicle. Having attained his object the insect withdraws, taking with him the pollen-masses, and visits another flower. And now occurs another device or adaptation no less marvellous than those of which mention has been made. The two anther-cases in an orchis are erect and nearly parallel the one to the other; the pollen-masses within them are of course in like case, as may be thus represented ||, but immediately the pollen-masses are removed movements take place in the caudicle so as to effect the bending of this stalk and the placing the pollen-mass in a more or less horizontal position, thus ═, or, as in the case of *O. pyramidalis*, the two pollen-masses originally placed parallel || diverge from the base like the letter V. The movements of the pollen-masses may readily be seen with the naked eye by thrusting the point of a needle into the base of the anther, when the disks adhere to the needle as they would do to the antenna of an insect, and may be withdrawn. Sometimes the lip is mobile and even sensitive to impressions, as are also certain processes of the column. In such cases the contact of an insect or other body with those processes is sufficient to liberate the pollen often with elastic force, even when the anther itself is not touched. In other orchids movements take place in different ways and in other directions. The object of these movements will be appreciated when it is remembered that, if the pollen-masses retained the original direction they had in the anther in which they were formed, they would, when transported by the insect to another flower, merely come in contact with the anther of that flower, where of course they would be of no use; but, owing to the divergences and flexions above alluded to, the pollen-masses come to be so placed that, when transplanted to another flower of the same species, they come in contact with the stigma and so effect the fertilization of that flower. These illustrations are comparatively simple; it would have been easy to select others of a more complicated nature, but all evidently connected with the visits of insects and the cross fertilization of the flower. In some cases the form of the male flowers is so different from that of the female that before the different flowers had been found on the same spike, and before the facts of the case were fully known, they were taken to be representatives of distinct genera.

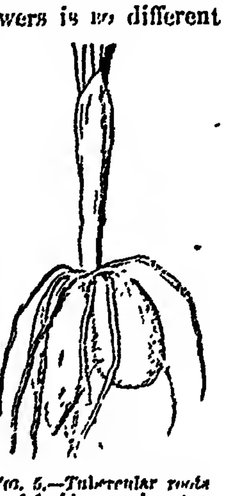

Fig. 5.—Tubercular roots of Orchis mascula, a terrestrial Orchid.

The floral structure is so curious that perhaps less attention has been paid to the vegetative organs than the peculiarities of their organization demand. We can only allude to some of these points. The orchids of British fields are all of terrestrial habit, and their roots are mostly tuberous (fig. 5), the tubers being partly radical partly bud-like in their character. There is often a marked alternation in the production of vegetative and flowering shoots respectively; and, sometimes, from various circumstances, the flowering shoots are not produced for several years in succession. This fact will account for the profusion with which

some orchids, like the common bee orchis for instance, are found in some seasons and their scarcity in others. Tropical orchids are mostly epiphytal,—that is, they grow upon trees without deriving nourishment from them. They are frequently provided with "pseudo-bulbs," large solid swellings of the stem, in the tissues of which water and nutritive materials are stored. Very generally, too, such plants have aerial roots, of thick or thin wire-like form, covered with a spongy white investment, the constituent cells of which are found under the microscope to contain spiral fibres tightly coiled up within them. By these "air-roots" the plants are able to absorb watery vapour and perhaps actual water.

The number of species of orchids is greater than that of any other monocotyledonous order—not even excepting grasses—amounting to between 4000 and 5000 at least. This large number is partly accounted for by the diligent search in all countries that has been made for these plants for purposes of cultivation,—they being held at present in the greatest esteem by plant-lovers, and prices being paid for new or rare varieties which recall the days of the tulipomania. It must be admitted, however, that orchid-lovers have better reasons to support their fancy than had the speculative growers and barterers of tulips.

The economic uses of orchids are not remarkable. When we have mentioned vanilla, which consists of the pods of an orchid, we have mentioned about the only economic product that now comes into market. Salep, still used in the Levant, consists of the dried tubers of some terrestrial orchid, and contains a relatively large amount of nutritious matter.

Cypripedium demands notice, inasmuch as it, with one or two other genera, constitutes a tribe of the order in which two stamens are present, one on each side of the column instead of one only at the top. What may be considered the normal number of stamens is, as has been said, six, arranged in two rows. In most orchids the only stamen developed to maturity is the posterior one of the three opposite to the lip (anterior before the twisting of the ovary), the other two, as well as all three inner ones, being entirely absent, or present only in the form of rudiments. In *Cypripedium* all three of the outer stamens are wanting, but the two lateral ones of the inner series are present, the third being undeveloped. This arrangement may be understood by reference to the following diagram, representing the relative position of the stamens in orchids generally and in *Cypripedium*. The letter L indicates the position of the labellum; the large figures indicate the developed stamens; the italic figures show the position of the suppressed stamens.

ORCHIL. See ARCHIL.

ORCHOMENUS, the name borne by two cities of ancient Greece.

I. A Bœotian city, situated in the angle between the Cephissus and its tributary the Melas, on a long narrow hill which projects south from Mount Acontium. Its position is exceedingly strong, being defended on every side by precipice or marsh or river, and it was admirably suited to be the stronghold of an early kingdom. The acropolis is at the north end of the hill, on a peak which is overhung by Acontium, but at a distance sufficient to be safe from an enemy with the weapons of early warfare posted on the mountain. At the foot of the acropolis are the springs of the Melas. Orchomenus was the capital of the Minyæ, a race famous in the half-legendary history of early Bœotia; the sway of the Minyæ once extended over Bœotia, including even Thebes, but the Æolic Bœotians who made Thebes their stronghold broke the power of the Orchomenian kings. The most remarkable relic of the early power of Orchomenus is the so-called "treasury," which is said to be the oldest in Greece. It was larger than the buildings of similar style at Mycenæ (see MYCENÆ), and the admiration which Pausanias expresses for it is justified by the beautiful ornamentation, especially of the roof, which has been brought to light by Schliemann's excavations. The monument, undoubtedly the tomb of some ancient ruler, or of a dynasty, lies outside the city walls. The worship of the Charites (see GRACES) was the great cultus of Orchomenus, and the site of the temple is now occupied by a chapel, the Κοίμησις τῆς Παναγίας. The Charites were worshipped under the form of rude stones, which had fallen from heaven during the reign of Eteocles; and it was not till the time of Pausanias that statues of the goddesses were placed in the temple. Near this was another temple dedicated to Dionysus, in whose festival, the Ἀγριώνια, are apparent the traces of human sacrifice in early times. The city was destroyed by the Thebans in the 4th century; the men were slain, and the women and children sold as slaves. About thirty years later, after the battle of Chæronea (338 B.C.), Philip of Macedon restored the city. The name is spelt on the dialectic inscriptions and coins Ἐρχόμενος. It is mentioned in the Homeric catalogue.

II. An Arcadian city, situated in a district of the same name, north of Mantinea and west of Stymphalus. The district was mountainous, but embraced two valleys,—the northern containing a lake which is drained, like all Arcadian lakes, by a *katabothron*; the southern lying under the city, separated from Mantinea by a mountain ridge called Anchisia. The old city occupied a strong and lofty situation; in the time of Strabo it was a ruin, but Pausanias mentions that a new town was built below the old. A primitive wooden image of Artemis Cedreatis stood in a large cedar tree outside the city. Orchomenus is mentioned in the Homeric catalogue with the epithet πολύμηλος. It sent soldiers to Thermopylæ and to Platæa. The native form of the name was Ἐρχόμενος.

ORDEAL (Anglo-Saxon *ordâl*, *ordæl*, judgment) corresponds to modern German *urtheil*, but bears the special sense of the mediæval Latin *Dei judicium*, a miraculous decision as to the truth of an accusation or claim. The word is adopted in the late Latin *ordalium*, French *ordalie*. The ordeal had existed for many ages before it was thus named in Europe. In principle, and often in the very forms used, it belongs to ancient culture, thence flourishing up to the mediæval European and modern Asiatic levels, but dying out before modern civilization. Some ordeals, which possibly represent early stages of the practice, are simply magical, being processes of divination turned to legal purpose. Thus in Burmah suits are still determined by plaintiff and defendant being each furnished with a candle, equal in size and both lighted at once,—he whose candle outlasts the other being adjudged, amid the acclamations of his friends, to have won his cause (Shway Yoe, *The Burman*, vol. ii. p. 254). Even quainter is a Dyak ordeal in Borneo, where the two parties are represented by two shell-fish on a plate, which are irritated by pouring on some lime-juice, and the one first moving settles the guilt or innocence (as has been before arranged) of its owner (St John, *Forests of the Far East*, vol. i. p. 89). The administration of ordeals has been much in the hands of priests, and they are more often than not worked on a theological basis, the intervention of a deity being invoked and assumed to take place even when the process is in its nature one of symbolic magic. For instance, an ancient divining instrument consisted of a sieve held suspended by a thread or by a pair of shears with the points stuck into its rim, and considered to move at the mention of the name to be discovered, &c. Thus girls consulted the "sieve-witch" (κοσκινόμαντις) about lovers (Theocr., *Idyll.*, iii. 31). This *coscinomancy* served in the same way to discover a thief, when, with prayer to the gods for direction, the names of the suspected persons were called over to it (Potter, *Greek Antiquities*, vol. i. p. 352). When a suspended hatchet was used in the same way to turn to the guilty, the process was called *axinomancy*. The sieve-

ordeal remained popular in the Middle Ages (see the description and picture in Cornelius Agrippa, *De Occ. Phil.*); it is mentioned in Hudibras (ii. 3):

> "... th' oracle of sieve and shears
> That turns as certain as the spheres."

From this ancient ordeal is evidently derived the modern Christian form of the key and Bible, where a Psalter or Bible is suspended by a key tied in at Psalm l. 18: "When thou sawest a thief, then thou consentedst with him"; the bow of the key being balanced on the fingers, and the names of those suspected being called over, he or she at whose name the book turns or falls is the culprit (see Brand, *Popular Antiquities*, ed. Bohn, vol. iii. p. 351).

One of the most remarkable groups of divinations passing into ordeals are those which appeal to the corpse itself for discovery of its murderer. The idea is rooted in that primitive state of mind which has not yet realized the full effect of death, but regards the body as still able to hear and act. Thus the natives of Australia will ask the dead man carried on his bier of boughs who bewitched him: if he has died by witchcraft he will make the bier move round, and if the sorcerer who killed him be present a bough will touch him (Eyre, *Australia*, vol. ii. p. 344). That this is no isolated fancy is shown by its recurrence among the negroes of Africa, where, for instance, the corpse causes its bearers to dash against some one's house, which accuses the owner of the murder (J. L. Wilson, *Western Africa*, p. 231; Waitz, vol. ii. p. 193). This somewhat resembles the well-known ordeal of the bier in Europe in the Middle Ages, which, however, seems founded on a different principle, the imagination that a sympathetic action of the blood causes it to flow at the touch or neighbourhood of the murderer. Apparently the liquefaction of the blood which in certain cases takes place after death may have furnished the ground for this belief. On Teutonic ground, this ordeal appears in the *Nibelungenlied*, where the murdered Siegfried is laid on his bier, and Hagen is called on to prove his innocence by going to the corpse, but at his approach the dead chief's wounds bleed afresh. The typical instance in English history is the passage of Matthew Paris, that after Henry II.'s death at Chinon his son Richard came to view the body, "Quo superveniente, confestim erupit sanguis ex naribus regis mortui; ac si indignaretur spiritus in adventu ejus, qui ejusdem mortis causa esse credebatur, ut videretur sanguis clamare ad Deum." In Shakespeare (*Rich. III.*, act 1, sc. 2):

> "O gentlemen, see, see! dead Henry's wounds
> Open their congeal'd mouths, and bleed afresh!"

At Hertford assizes (4 Car. I.) the deposition was taken as to certain suspected murderers being required to touch the corpse, when the murdered woman thrust out the ring finger three times and it dropped blood on the grass (Brand, vol. iii. p. 231); and there was a case in the Scottish High Court of Justiciary as late as 1668 (T. F. Thiselton Dyer, *Folklore of Shakespeare*, p. 487). Durham peasants, apparently remembering the old belief, still expect those who come to look at a corpse to touch it, in token that they bear no ill-will to the departed (W. Henderson, *Folklore of Northern Counties*, p. 57).

Certain ordeals are closely related to oaths, so that the two shade into one another. Let the curse which is to fall on the oath-breaker take effect at once, it then becomes a sign condemning the swearer,—in fact, an ordeal. Thus the drinking of water on which a curse or magical penalty has been laid is a mere oath so long as the time of fulfilment is unfixed (see OATH). But it becomes an ordeal when, as in Brahmanic India, the accused drinks three handfuls of water in which a sacred image has been dipped: if he is innocent nothing happens, but if he is guilty sickness or misfortune will fall on him within one to three weeks (for accounts of these and other Hindu ordeals see Ali Ibrahim Khan in *Asiatic Researches*, vol. i. p. 389, and Stenzler's summary in *Z. D. M. G.*, vol. ix.). The earliest account of such an ordeal is in Numbers v., which describes the mode of administering to a woman charged with unfaithfulness the bitter water mixed with the dust of the tabernacle floor, with the curse laid on it to cause her belly to swell and her thigh to fall if guilty. Ewald (*Antiquities of Israel*, 236) regards the draught as in itself harmless, and the operation of this curse on the guilty as due to the influence of the mind on the body. But the term "bitter" is applied to the water before it has been cursed, which suggests that it already contained some drug, as in the poison-water ordeal still in constant use over a great part of Africa. Thus the red water of Guinea is a decoction made by pounding in a wooden mortar and steeping in water the inner bark of one of the mimosas, producing a liquor like that of a tan-vat, astringent, narcotic, and when taken in sufficient quantity emetic. The accused, with solemn ceremony and invocation, drinks freely of it; if it nauseates him and he throws it up he is triumphantly acquitted, but if he becomes dizzy he is guilty, and the assembly fall on him, pelt him with stones, and even drag him over the rocks till he is dead. Here the result of the ordeal depends partly on the patient's constitution, but more on the sorcerer who can prepare the proper dose to prove either guilt or innocence. Among the various drugs used in different parts of Africa are the *mbundu* root, the Calabar bean, the tangena nut (*Tanghinia venenifera*, a strong poison and emetic). The sorcerers who administer this ordeal have in their hands a power of inflicting or remitting judicial murder, giving them boundless influence (details in J. L. Wilson, *Western Africa*, pp. 225, 398; Burton, *Lake Regions of Central Africa*, vol. ii. p. 357; Bosman, "Guinea," in *Pinkerton's Voyages*, vol. xvi. pp. 398, &c.). The poison-ordeal is also known to Brahmanic law, decoction of aconite root being one of the poisons given, and the accused if not sickening being declared free (Stenzler, *l.c.*). Theoretically connected with the ordeal by cursed drink is that by cursed food, which is, however, distinguished among this black catalogue by being sometimes an effectual means of discovering the truth. The ordeal by bread and cheese, practised in Alexandria about the 2d century, was practically the same as that known to English law five to ten centuries later as the *corsned* or "trial slice" of consecrated bread and cheese which was administered from the altar, with the curse that if the accused were guilty God would send the angel Gabriel to stop his throat, that he might not be able to swallow that bread and cheese. In fact, if guilty and not a hardened offender he was apt to fail, dry-mouthed and choking through terror, to get it down. The remembrance of this ancient ordeal still lingers in the popular phrase, "May this bit choke me if I lie!" In India the corresponding trial by rice is prescribed in the old laws to be done by suspected persons chewing the consecrated grains of rice and spitting them out, moist and untinged with blood, on a banyan leaf; this or the mere chewing and swallowing of a mouthful of rice-grains is often used even by the English as means of detecting a thief. A classical mention of the ordeals by carrying hot iron in the hands and by passing through the fire is made more interesting by the guards who offer to prove their innocence in this way offering further to take oath by the gods, which shows the intimate connexion between oaths and ordeals (Soph., *Ant.*, 264; see also Æschyl. *fr.* 284).

> ἦμεν δ' ἕτοιμοι καὶ μύδρους αἴρειν χεροῖν
> καὶ πῦρ διέρπειν, καὶ θεοὺς ὁρκωμοτεῖν
> τὸ μήτε δρᾶσαι μήτε τῳ ξυνειδέναι
> τὸ πρᾶγμα βουλεύσαντι μήτ' εἰργασμένον.

The passing through the fire is described in the Hindu codes of Yâjnavalkya and others, and is an incident in Hindu poetry, where in the *Râmâyana* the virtuous Sitâ thus proves her innocence to her jealous husband Râma (Stenzler, p. 669; Pictet, *Origines Indo-Européennes*, part ii. p. 457). It was not less known to European law and chronicle, as where Richardis, wife of Charles the Fat, proves her innocence by going into a fire clothed in a waxed shift, and is unhurt by the fire (Grimm, *Deutsche Rechtsalterthümer*, p. 912). Yet more minutely prescribed in the Hindu ordeal-books is the rite of carrying the glowing hot iron seven steps, into the seven or nine circles traced on the ground, the examination of the hands to see if they show traces of burning, and the binding them up in leaves. The close historical connexion of the Hindu ordeal laws with the old European is shown by the correspondence of minute details, as where in a Scandinavian law it is prescribed that the red-hot iron shall be carried nine steps (Grimm, *op. cit.*, p. 918). In Anglo-Saxon laws the iron to be carried was at first only one pound weight, but Athelstan's law (in *Ancient Laws and Institutes of England*, iv. 6) enacts that it be increased to weigh three pounds. Another form well known in old Germany and England was the walking barefoot over glowing ploughshares, generally nine. The law-codes of the early Middle Ages show this as an ordinary criminal procedure (see the two works last referred to), but it is perhaps best remembered in two non-historical legends. The German queen Kunigunde, "hæc dicens stupentibus et flentibus universis qui aderant, vomeres candentes nudo vestigio calcavit et sine adustionis molestia transiit" (*Vita Henrici*, ap. Canisium, vi. 387). Queen Emma, mother of Edward the Confessor, accused of familiarity with Alwyn bishop of Winchester, triumphantly purges herself and him by the help of St Swithin,—each of the two thus acquitted giving nine manors to the church of Winchester, in memory of the nine ploughshares, and the king being corrected with stripes (John Bromton; see Freeman's *Norm. Conq.*, vol. ii. App.). To dip the hand in boiling water or oil or melted lead and take out a stone or ring is another ordeal of this class. The traveller may find some of these fiery trials still in use, or at least in recent memory, in barbaric regions of Africa or further Asia,—the negro plunging his arm into the caldron of boiling oil, the Burman doing feats with melted lead, while the Bedouin will settle a conflict of evidence by the opposing witnesses licking a glowing hot-iron spoon (Burckhardt, *Arabien*, pp. 98, 233). This latter feat may be done with safety by any one, provided the iron be clean and thoroughly white hot, while if only red-hot it would touch and burn the tongue. Probably the administerers of the ordeal are aware of this, and of the possibility of dipping the hand in melted metal; and there are stories of arts of protecting the skin (see the recipe in Albertus Magnus, *De Mirabilibus*), though it is not known what can be really done beyond making it horny like a smith's, which would serve as a defence in stepping on hot coals, but not in serious trials like that of carrying a heavy red-hot iron. The fire-ordeals are still performed by mountebanks, who very likely keep up the same means of trickery which were in official use when the accused was to be acquitted. The actual practice of the fire ordeal contrasts shamefully with its theory, that the fire rather than harm the innocent restrained its natural action. Thus it stands in the Hindu code of Manu (viii. 115): "He whom the flame does not burn, whom the water does not cast up, or whom no harm soon befals, is to be taken as truthful in his oath." The water-ordeal here referred to is that well known in Europe, where the accused is thrown bound into the water, which receives him if innocent, but rejects him if guilty. The manner of carrying out this test is well explained in the directions given by Archbishop Hincmar in the 9th century: he who is let down into the water for trial is to be fastened by a rope, that he may not be in danger if the water receives him as innocent, but may be pulled out. In the later Middle Ages this ordeal by "swimming" or "fleeting" became the most approved means of trying a suspected witch: she was stripped naked and cross bound, the right thumb to the left toe, and the left thumb to the right toe. In this state she was cast into a pond or river, in which it was thought impossible for her to sink. (Brand, vol. iii. p. 21.) The cases of "ducking" witches which have occurred in England within the last few years are remains of the ancient ordeal.

If there is one thing that may be predicated of man in a state of nature it is that two disputants tend to fight out their quarrel. When in the warfare of Greeks and Trojans, of Jews and Philistines, of Vandals and Alamans, heroes come out from the two sides and their combat is taken to mark the powers of the opposing war-gods and decide the victory, then the principle of the ordeal by battle has been practically called in. Among striking instances of the Teutonic custom which influenced the whole of mediæval Europe may be cited the custom of the Franks that the princes, if they could not quell the strife, had to fight it out between themselves, and Wippo's account of the quarrel between the Christian Saxons and the Pagan Slavs as to which broke the peace, when both sides demanded of the emperor that it should be settled by duel, which was done by choosing a champion on each side, and the Christian fell. The Scandinavian term "holmgang" refers to the habit of fighting duels on an island. A passage from old German law shows the single combat accepted as a regular legal procedure: "If there be dispute concerning fields, vineyards, or money, that they avoid perjury let two be chosen to fight, and decide the cause by duel" (Grimm, *Rechtsalterth.*, p. 928). In England, after the Conquest, trial by combat superseded other legal ordeals, which were abolished in the time of Henry III. Among famous instances is that of Henry de Essex, hereditary standard-bearer of England, who fled from a battle in Wales, in 1158, threw from him the royal standard, and cried out that the king was slain. Robert de Montfort afterwards, accusing him of having done this with treasonable intent, offered to prove his accusation by combat, and they fought in presence of Henry II. and his court, when Essex was defeated, but the king spared his life, and, his estate being confiscated, he became a monk in Reading Abbey. A lord often sent his man in his stead to such combats, and priests and women were ordinarily represented by champions. The wager of battle died out so quietly in England without being legally abolished that in the Court of King's Bench in 1818 it was claimed by a person charged with murder, which led to its formal abolition (Ashford *v.* Thornton in Barnewall and Alderson, 457; see details in H. C. Lea, *Superstition and Force*, ii.). A distinct connexion may, however, be traced between the legal duel and the illegal private duel, which has disappeared from England in our own time, but still flourishes in France and Germany. (E. B. T.)

ORDER, or ORDINATION (Ordo seu sacra ordinatio), one of the seven sacraments of the Roman Catholic Church (see SACRAMENT), is the rite by which the ministers of that church, in their respective ranks as priests, deacons, subdeacons, acolytes, exorcists, lectors, and doorkeepers (ostiarii), receive power and grace for the discharge of their several functions. The nature of these functions is stated in separate articles (see ACOLYTE, &c.). The sacrament of order or ordination cannot be administered except by a bishop. The seven ranks just mentioned are themselves called "orders," the first three being distinguished as the

"major" or "holy" orders (ordines majores, sacræ); the others are "minor" (ordines minores). Within the order of the priesthood itself there are various degrees of power and dignity:—(1) that of priest, pure and simple; (2) that of bishop; (3) that of archbishop; (4) that of patriarch (see BISHOP, &c.). For a brief statement of the points of difference as to ecclesiastical orders between the Roman Catholic and the Orthodox Greek Churches, see vol. xi. p. 159. The Church of England expressly recognizes the diaconate and the priesthood, but no others, as distinct orders; bishops and archbishops are "ordained and consecrated." In the 25th Article the name of sacrament is deliberately withheld from orders. Compare the articles CLERGY, EPISCOPACY, INDEPENDENTS, MONACHISM, PRESBYTERIANISM.

ORDERICUS VITALIS, the author of a *History* of considerable value in relation to England and Normandy in the 11th and 12th centuries, was born in the year 1075 at Atcham near Shrewsbury. His father, Odeler of Orleans, was one of the followers of Roger Montgomery, a powerful baron who had accompanied William the Conqueror from Normandy, and in whom that monarch reposed especial confidence. Roger had at one time cruelly despoiled the abbey of St Evroul en Ouche, and in his latter years sought to make reparation by bestowing large gifts of benefices and lands on the society. In this manner Odeler also became interested in St Evroul. He was a married priest, and Orderic, the eldest of his three sons, who had at first been sent by him to receive his education at Shrewsbury, was now at the age of ten years dedicated to the monastic life and sent to St Evroul. It was a Benedictine foundation, and at this time perhaps the most celebrated of all the schools in Normandy (*Gallia Christiana*, xi. 814-6). On the 21st of September 1085 the youthful Orderic received the tonsure and was admitted one of the oblates of the monastery. It was the feast of St Maurice, the commander of the legendary Theban legion, and Orderic's name, which seems to have been displeasing to the Norman ear, was now changed into that of Vitalis, one of Maurice's lieutenants. In March 1093 he was ordained a deacon, but was not admitted to priestly orders until 1107. We have it on his own testimony that he was treated with kindness in his new home, and his uneventful life was chiefly passed in a routine of religious observances and of such studies as the Benedictine rule was then interpreted to admit; but from this number, he tells us, pagan history was excluded. The discipline of the society at St Evroul was well maintained, and not a few of its members were worthy representatives of that spirit of devotion to learning by which their order was long so honourably distinguished. Orderic's superiors appear to have soon discerned his aptitude for literary labours, and at the suggestion of two of their number (Roger and Guérin) he first commenced to write the history of the foundation. Among his fellow-monks were men who had taken part in the expeditions of the Normans in Italy and Sicily, in the Crusades, and in the wars waged by William the Conqueror and his sons, and to such associations, as well as to the advantages which a resident at St Evroul would enjoy owing to its being a great centre of intercommunication, we must attribute much of the remarkably varied and minute information with which the *Historia* abounds. Travel, again, appears to have had for Orderic a special charm; and, notwithstanding the difficulties interposed by his monastic vow, he twice revisited his native country, Croyland and Worcester having been his principal places of sojourn. We also find him at Cambrai, and in 1132 at Cluny at a great gathering of its celebrated order. In the year 1141, being, as he tells us, worn out with age and infirmities, he was fain to bring his historical labours to a close, and it is inferred that his death occurred soon after. Although compelled to quit his native country at so early an age, Orderic seems always to have felt himself an exile. In the title of his work he is careful to describe himself as "Angligena," and throughout the narrative he gives special prominence to whatever relates to England.

The *Historia Ecclesiastica* is divided into three parts. Of these the first, in two books, gives an outline of the history of the church from the commencement of the Christian era to the death of Pope Leo IV. in 855, a list of the popes from that date to Innocent II. being appended. The second part—the first in order of composition (see *supra*)—is the *Historia Uticensis*, or history of the monastery of St Evroul from its foundation by Abbot Ebrulf in the year 560 to the narrator's own time; it contains many interesting sketches of the abbots and other members or benefactors of the society. The third part—the only genuinely historical portion of the work—is in seven books, and is devoted to a general account of events in Western Christendom from Carolingian times down to the year 1141. With the year 1084 (after a considerable break in the narrative) the work begins to assume its peculiar value as a storehouse of information with respect to the history and social condition of England and Normandy in the latter part of the 11th and first half of the 12th century. In striking contrast to the ordinary chroniclers of his age, Orderic collected and recorded with scrupulous care numerous facts and incidents which others would have deemed too insignificant for notice. But there is no work relating to the same period, says Guizot, which throws so much light on the political, civil, and religious aspects of society in the West, and the conditions of feudal, monastic, and ordinary life. These merits, however, are in no slight degree obscured by Orderic's singularly involved style and turgid diction, while his absolute disregard of method renders his narrative at times difficult to comprehend and follow.

In addition to the *Historia* there exists in the library at Rouen a manuscript edition of the Norman history of William of Jumièges, which M. Leopold Delisle feels no hesitation in assigning to Orderic (see his *Lettre à M. Jules Lair*, 1873).

The best edition of the *Historia* is that edited by M. Auguste Le Prévost, in five volumes (1838-55). In the concluding volume (pp. i.-cvi.) there is an admirable account and criticism of Orderic by M. Leopold Delisle. The edition in Migne's *Patrologia*, vol. clxxxviii., though a later publication, is a reprint of the less accurate text of Duchesne. A French translation by M. Guizot, in 4 vols., 8vo, was published at Caen in 1826-27; and there is an English version (with Guizot's preface) by Thomas Forester, 4 vols., 1853-56, in Bohn's *Antiquarian Library*.

ORDERS OF KNIGHTHOOD. See KNIGHTHOOD.

ORDINARY is the legal name for a bishop or other person with original ecclesiastical jurisdiction when exercising the functions of his office. He is so called "quia habet ordinariam jurisdictionem in jure proprio et non per deputationem" (Coke upon Littleton, 96 *a*). The word is also used in a non-ecclesiastical sense. By the Divorce Act, 1857, 20 and 21 Vict. c. 85 *sq.*, the judge appointed by that Act had the title of Judge Ordinary. This title has now, however, become obsolete owing to the incorporation of the Divorce Court with the High Court of Justice by the Judicature Act, 1873. In Scotland the judge before whom a cause depends in the Outer House is called the Lord Ordinary in that cause, and the judge who officiates in the Bill Chamber is called the Lord Ordinary on the Bills. In the United States the ordinary possesses, in the States where such an officer exists, powers vested in him by the constitution and acts of the legislature. In South Carolina he is a judicial officer.

ÖREBRO, one of the most important cities in Sweden, the chief town of a province of its own name, lies on both sides of the Svartå about a mile above its entrance into Lake Hjelmar, and 160 miles by rail west of Stockholm. In great part rebuilt since the fire of 1854, it has quite a modern appearance. Besides the principal church, dating from the close of the 14th or beginning of the 15th century, but modernized in the 19th, the more conspicuous buildings are the castle, on an island in the middle of the stream, the new Gothic town-house, the theatre, and the hospital. In front of the town-house stands a statue by Qvarnström, erected in 1865, representing Engelbrecht, the nobleman who was elected administrator of the kingdom in 1435; and

in front of the principal hotel is an obelisk in honour of the Swedish Reformers Olaus and Laurentius Petri. Örebro has railway connexion with the mining districts round about, and carries on a trade with Stockholm by means of the Hjelmar Canal. The population was 2147 in 1749, 4227 in 1840, 9056 in 1865, and 11,785 in 1880.

Örebro was in existence in the 11th century. Its castle, erected by Birger Jarl in the 13th century, plays an important part in the early annals of Sweden: and no fewer than twenty diets or important assemblies have been held either in castle or town. It is sufficient to mention the Örebro concilium of 1537, the diet of 1540 in which the crown was declared hereditary, and that of 1810 when Bernadotte was elected crown prince.

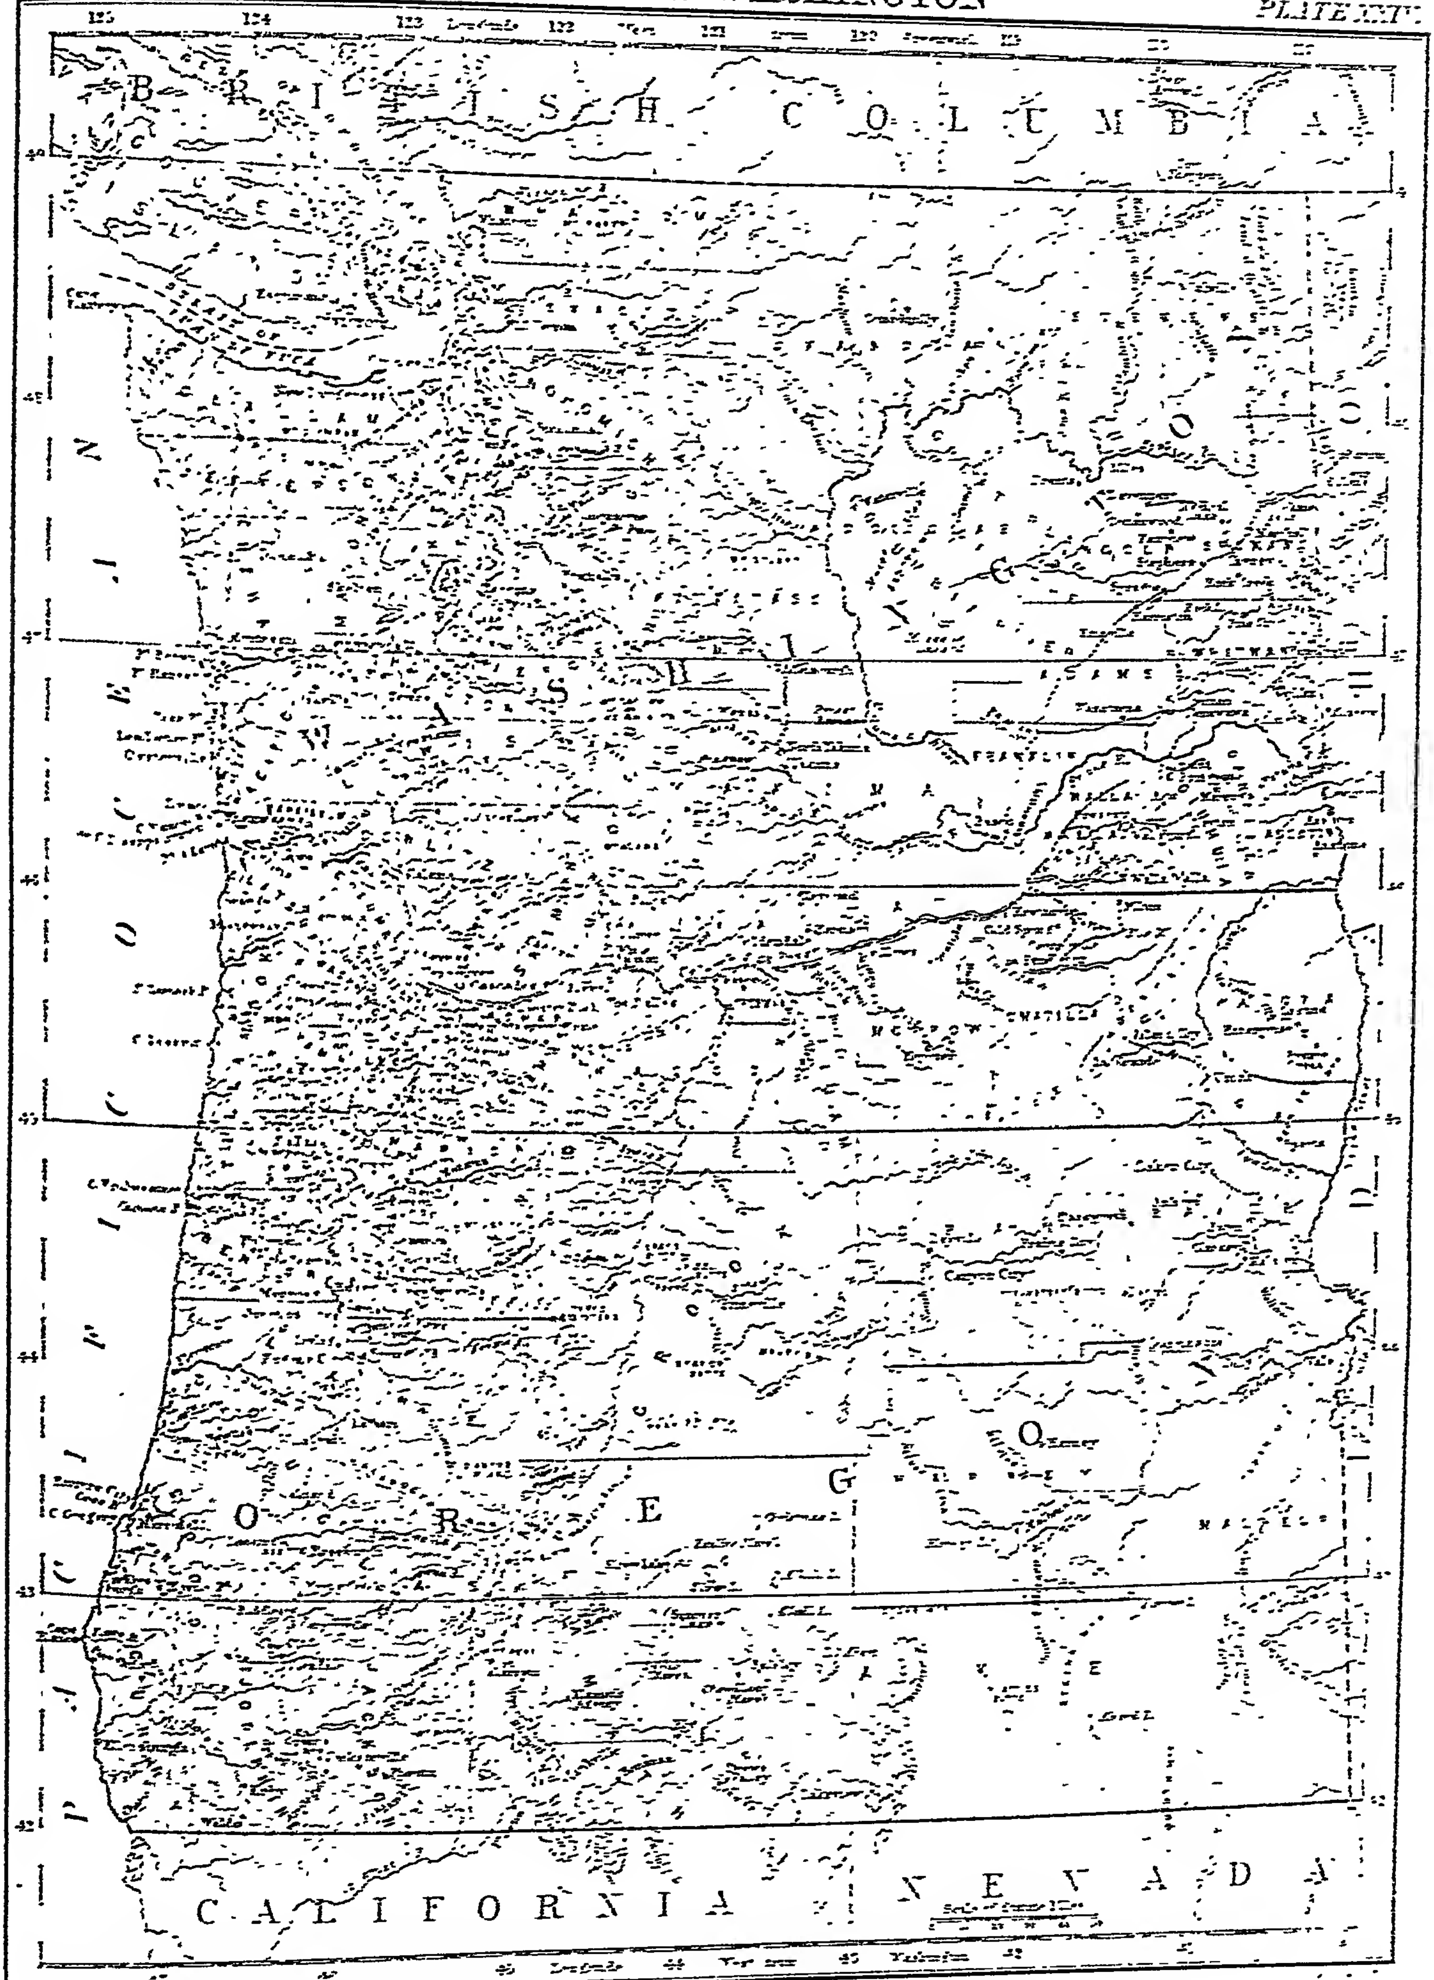
Plate XXIV. OREGON, one of the Pacific States of the American Union, is bounded N. by Washington Territory, E. by Idaho Territory, S. by Nevada and California, and W. by the Pacific, and lies between 42° and 46° 15′ N. lat. and 116° 45′ and 124° 30′ W. long. It has an area of 94,560 square miles, besides 1470 square miles of water-surface; its average width from east to west is 345 miles, and from north to south 276 miles.

The State is divided by the Coast, Cascade, and Blue Mountains into well-marked sections. The Cascade range extends in an almost due north and south direction, parallel with the Pacific coast, and a little over 100 miles from it, entirely across the State, and thence northerly through Washington Territory into British Columbia; still farther north it forms the undefined boundary between the latter province and Alaska. In Oregon the range is heavily timbered, chiefly with coniferous evergreens, the principal trees being yellow, sugar, and scrub pine, yellow and white fir, several varieties of spruce, red and white cedar, yew, juniper, tamarack, and cypress; there is also a considerable quantity of maple, ash, and alder, and some oak in the western foot-hills to the south. Its most striking feature is the number of beautiful cone-shaped peaks, rising above the line of perpetual snow. Several quite low passes exist, which, however, are very little used. Commencing at the southern boundary of Oregon, the first of these peaks is Mount Pitt (9818 feet), flanked on all sides by outlying spurs and foot-hill ranges. Forty miles to the north stands Mount Scott (9016 feet), the eastern slope of which, covered with ashes and light débris, is comparatively easy of ascent; on the west the bluffs are almost perpendicular walls of igneous rock, sheltering great masses of snow. Mount Scott overlooks Mystic or Crater Lake, an elliptically-shaped basin of water about 5 miles long by 3 miles broad, entirely surrounded by unbroken cliff-walls ranging from 500 to 2000 feet; this occupies the crater of a gigantic old volcano of which Mount Scott is a portion of the eastern rim, all the rest having been carried away by erosion and other causes. Forty miles farther north is Diamond Peak (8807 feet high), which also gives evidence of being the south-eastern portion of an old crater rim. The portion of the mountain-chain from Mount Scott to Diamond Peak was a region of numerous volcanoes and of very extensive local lava-flows. It has a very high average elevation, and in it all the principal rivers of western Oregon have their sources: the Willamette, running to the north-west; the Des Chutes, running to the north-east; the head-water streams of Klamath river, flowing to the south, and breaking through the range to the west; the Rogue river, flowing to the south-west; and the Umpqua to the west and north. The Three Sisters (in reality five) are the next marked peaks (about 9000 feet); they seem to be portions of an old crater rim, 12 miles in diameter, now broken and worn away. Mount Jefferson (about 10,200 feet) comes next, and then Mount Hood, the highest of all (11,225 feet). To the north of this the Columbia breaks through the range, having cut for itself a cañon, 4000 feet in depth, through the overlying lava and far into the previously-formed conglomerate on which it rests.

Eastern Oregon is in its southern part a vast volcanic plateau, rocky and sterile, lacking water, and possessing few natural attractions. The great interior basin, without outlet to the ocean, extends far up into the State. In this region are a few lakes, generally alkaline and marshy sinks, fed by little streams which have their origin in the small neighbouring mountain masses. The principal vegetation consists of several varieties of sage brush, dwarf pine, and juniper, the last furnishing the winter food of immense numbers of deer, which, during the summer, range through the highlands and glens of the Cascades. Many small peaks and ranges rise from the plateau, all probably of volcanic origin, and some of them made up almost exclusively of blocks and masses of obsidian. From near its junction with the Boisée to the northern line of the State the Snake river forms the eastern boundary of Oregon, and nowhere in the world is there to be found a more perfect and impassable barrier than is formed by this river and its tremendous cañon, of which the walls (consisting of basaltic and kindred rocks) are from 2000 to 5000 feet in height, and so steep and precipitous that the most skilful mountaineer can scarcely find a place to ascend or descend them. In several cases the columnar black basalt takes wonderful shapes and produces most fantastic effects. The Snake in this part of its course is not navigable, and can never be made so. The northern portion of eastern Oregon is far superior in all its physical characteristics to the southern. Confused masses, known as the Blue and Powder River Mountains, lie in the north-east, modifying the climate for the better, and giving many rich valleys and table-lands to the agriculturist. The Grande Ronde, Umatilla, John Day, Burnt, and Powder rivers are the principal streams, and their main and tributary valleys are very lovely. The mountains are covered with pine of a very fair quality, with fir, cedar, and some maple, all of which is being rapidly cleared away. In the valleys cottonwood, willow, birch, aspen, and poplar grow freely. The hills are well stocked with the larger game, as bear, deer, mountain sheep, grey wolves, panthers, foxes, &c., the valleys and lakes with feathered game in considerable variety, and the streams with trout and salmon. Many mines of gold and silver have been found in the Blue and Powder River Mountains, but none of remarkable richness. Nearly all the untimbered plains and valleys of north-eastern Oregon are covered with a rich growth of the hardy and nutritious "bunch grass." The soil is very deep, and, coming, as it does, from the disintegration of volcanic rocks, is very fertile. The Des Chutes river drains most of the eastern slope of the Cascades, flowing in a wild turbulent stream through a deeply-cut cañon. The river is so swift, crooked, and with such rugged banks and so many jagged rocks that it is deemed impracticable even for the lumberman's use in floating logs to the Columbia.

The warm oceanic current from Japan, flowing south along the coast, is the cause of the mild climate of western Oregon, and of the heavy and incessant rains with which it is visited. These rains, continued through the centuries, have chiselled away the mountains, and, with other geological agencies, produced the three principal valleys into which this portion of the State may be considered as divided,—the Willamette, Umpqua, and Rogue river valleys. The Willamette valley has an area of about 8000 square miles, and contains more than half the population and wealth of the entire State. Its lower portions are level loamy plains, covered with rank grass, and here and there great areas of lowland timber, such as alder, maple, ash, cottonwood, poplar, &c., and a vast profusion of

OREGON & WASHINGTON



shrubbery. All about these lower plains are well-marked terraces, composing the higher levels, and from these east, west, and south to the encircling mountains, are spread away the rolling fertile uplands, gradually merging into the dense fir and pine forests which crown the higher summits. Many things attest the former presence of an arm of the sea extending from Puget Sound to the southern end of the valley. Many basaltic ridges yet remain, but this rock has been largely washed away. Western Oregon is well supplied with the ordinary building stones, as granite, syenite, and sandstone. Marble and limestone are found in the extreme south-west, and a valuable cement stone in the valley of the Umpqua. The Umpqua is a rapid mountain stream, and its valley is narrow but extremely fertile. This and Rogue river break through the Coast range in cañons, deep, rugged, and heavily timbered. The valley of Rogue river is beautiful, with a delightful climate, but it has always been very difficult of access, and has only now been reached for the first time from the north by the railroad. Much gold has been taken from the placer mines of the valley, and the sands and gravels of nearly all the tributary valleys carry the precious metal. The country lying between the Coast range and the ocean is narrow and very rugged, with some small cultivable valleys very difficult of access. There are no good harbours on the coast, but the Government is making efforts to improve Coos and Yaquina bays and Port Orford.

The Columbia river enters the Pacific Ocean near the 46th degree of north latitude; it drains by means of its tributaries the western slope of the Rocky Mountains, from about the 42d to the 53d parallel, a distance of 900 miles. The area of its drainage-basin is nearly 245,000 square miles. The route of communication by the Columbia has been of the greatest importance in the early development of Oregon, and its value increases daily. The head of navigation for sea-going ships is at Portland, about 100 miles up the Columbia and 12 miles up the Willamette. From this point up to the Cascades, river craft go freely with plenty of water at all seasons of the year, with, generally, the exception of a short time each winter when the river is frozen. The cascades of the Columbia are due north from Mount Hood, just on the central line of the range where it is cut through by the river. The obstruction to navigation here is complete; but the Government has for several years been engaged in the construction of a canal which will make navigation continuous 45 miles farther, up to the Dalles, at the eastern base of the Cascades. Here there is another total obstruction, the river flowing swiftly through intricate channels, which seem to have been originally great cracks in a field of lava; surveys have been made, however, and plans prepared for improvements. Above the Dalles the Columbia is navigable for 190 miles and the Snake for 180. The Northern Pacific Railroad passes down on the Oregon side, through the cañon of the Columbia. The Columbia is noted for its beautiful scenery, for the great quantity of salmon taken from its waters, and for the dreaded bar at its mouth. The dangers from this bar have been greatly lessened of late years by improved pilotage and more accurate knowledge of the phenomena; and further ameliorations by the general Government are in contemplation.

The south-west warm winds from the Pacific distribute vapours over western Oregon abundantly in autumn, winter, and spring in dews, fogs, rains, and occasional snows, and over eastern Oregon in less amounts. The north-west summer winds are cool. The average temperature in western Oregon is—in spring 52°, in summer 67°, in autumn 53°, and in winter 39° Fahr. The thermometer seldom rises above 90° in the hottest days of the summer, and rarely falls below 20° in the winter. In the thirteen years 1849-51 and 1858-68, two-thirds of the days were pleasant, and only one-third were either showery or rainy or snowy in the north-west part of the State. In the Willamette valley the average yearly rainfall is 44 to 54 inches, which is about the same as at Philadelphia and at Davenport (Iowa). In the Umpqua and Rogue river valleys it is somewhat less. Thunder-storms seldom occur in the State, and cyclones and tornadoes are unknown.

Geology.—The geological history of the Cascade and Coast ranges of Oregon is very interesting. For an immense period before these ranges existed the primeval ocean washed the western shores of the great Rocky Mountain chain, and throughout the Palæozoic era and the whole Triassic and Jurassic periods of the Mesozoic era numerous rivers kept bringing down débris until an enormously thick mass of off-shore deposits had accumulated. This marginal sea-bottom became the scene of intense aqueo-igneous action in its deeply-buried strata, producing a line of weakness, which, yielding to the horizontal thrust produced by the secular contraction of the interior of the earth, was crushed together and swollen up into the Sierra Nevada and Cascade Mountains at the end of the Jurassic period. The range thus produced, as far as can be ascertained, was not of very great height, though probably higher to the south than to the north. It existed for unknown centuries, and in its turn was the theatre of erosion and plant-growth, and was roamed over by the now extinct fauna of the Cretaceous and Tertiary periods. It was not yet covered by the great lava-flow and mountain range of the modern Cascades, but by forests of conifers and oaks. Beneath the overlying lava, where the Columbia breaks through the range, there is found along the water's edge, and for about 15 feet upwards, a very coarse conglomerate of rounded porphyritic pebbles and boulders of all sizes up to 6 feet in diameter, held together by an imperfectly-lithified earthy paste. Above this conglomerate is a very distinct irregular old ground-surface bed, in which are found silicified stumps with roots extending over a diameter of 20 feet and penetrating into the boulder material beneath, evidently *in situ*. Resting directly on this forest ground-surface, and therefore enclosing the erect stumps, is a layer of stratified sandstone, 2 or 3 feet thick, filled with beautiful and perfect impressions of leaves of several kinds of forest trees, possibly of the very trees about whose silicified bases they are found; this layer is not continuous, like the ground-surface on which it rests. Above this leaf-bearing stratum rests a coarse conglomerate similar to that beneath at the water-level. Scattered about in the lower part of this upper conglomerate and in the stratified sandstone, and sometimes lying in the dirt-bed beneath it, fragments of silicified drift-wood are found. Above this last conglomerate, and resting upon it, rise the layers of lava, mostly columnar basalt, one above another, to a height of more than 3000 feet. The following order of events has been deduced from these facts by Professor Le Conte, their first observer.

The region of the Columbia river was a forest, probably a valley, overgrown by conifers and oaks. The subsoil was a coarse boulder drift produced by erosion of some older rocks. An excess of water came on, either by floods or changes of level, and the trees were killed, their leaves shed and buried in mud, and their trunks rotted to stumps. Then came on a tumultuous and rapid deposit of coarse drift, containing drift-wood, which covered up the forest ground and the still remaining stumps, to a depth of one, perhaps several, hundred feet. The surface thus formed was eroded into hills and dales, and then followed the outburst of lava in successive flows, and the silicification of the wood and cementation of the drift by the percolation of the hot alkaline waters containing silica. Finally followed the process of erosion by which the present stream, channels, and valleys, whether main or tributary, have been cut to their enormous depths. The great masses of sediment sent down to the sea by the erosion of the primary Cascade range, forming a thick off-shore deposit, gave rise in turn at the end of the Miocene to the upheaval of the Coast range, the Cascade Mountains being at the same time rent along the axis into enormous fissures, from which outpoured the grand lava-floods, building the mountains higher, and covering the country for great distances. This is probably the grandest lava-flow known to geology, covering as it does an area of about 200,000 square miles. Commencing in middle California as separate streams, in northern California it becomes a flood, completely mantling the smaller and flowing around the greater inequalities. In northern Oregon and Washington it becomes an absolutely universal flood, beneath which the whole original face of the country, with its hills and dales, mountains and valleys, lies buried several thousand feet. It covers the greater portion of northern California and north-western Nevada, nearly the whole of Oregon, Washington, and Idaho, and runs far into British Columbia on the north. The average thickness is

probably not far from 2000 feet, and the greatest (shown where the Columbia, Des Chutes, Snake, Salmon, and other rivers cut through it) about 4000 feet. To produce this many successive flows took place, and a very long period of time must have elapsed during which the volcanic actions were going on. During the period of these Cascade eruptions the Coast range was being slowly elevated, and became in its turn the scene of local volcanic action, which was, however, not very severe. At last the great fissure eruptions in the Cascades drew to a close by the fissures becoming blocked up; the volcanic action was concentrated in a few localities, and the period of crater-eruptions followed. These eruptions continued for a long time, almost to our own day, and to them the upbuilding of the snow-clad peaks is due. By the formation of the Cascade range there came into existence a grand interior basin, the waters of which collected into secondary reservoirs, some of very large extent, and were carried off by the rivers which have cut their way from the interior to the sea. The Columbia and its tributaries drained the northern part of this immense basin, and it was at this period, doubtless, that the Great Salt Lake of Utah assumed its once colossal proportions and found its outlet to the sea by the Snake and Columbia rivers. Then came the lava-floods, since denuded in places, exposing the Tertiary and Cretaceous beds, and furnishing evidence of the former condition of the region by the fossils found therein. At the end of the Miocene the Coast range was upheaved, and the lava-flows from the Cascade fissures commenced, but it was long before these reached the entire extent of the basins of Oregon, which continued to exist and to be endowed with life well into the Pliocene. The principal fossil beds of the State are those of the John Day, Des Chutes, and Grande Ronde countries, and near Christmas Lake in southern Oregon. The Glacial, Champlain, and Terrace epochs are very well illustrated in several places, and have left marked evidences of their existence.

Fauna and Flora.—Since the occupation of the State by civilized men the grizzly, black, and cinnamon bears, grey wolf, coyote, panther, catamount, wild cat and polecat, deer, antelope, elk, and mountain sheep have slowly retreated from the settlements to the recesses of the hills. Fur-bearing animals have increased since the Hudson's Bay Company withdrew from the country. Silver foxes, martens, hares, rabbits, squirrels, raccoons, porcupines, beaver, otter, musk-rats, and seals are found in greater or less abundance within the State. Salmon, sturgeon, trout, holibut, smelt, and other fish in countless numbers exist in the Columbia and its branches and in the bays and coast rivers, and oysters, shrimps, crabs, and clams along the shores. Eagles, hawks, cormorants, pelicans, gulls, cranes, albatross, vultures, buzzards, ravens, crows, jays, robins, swallows, sparrows, rice-birds, yellow-birds, humming-birds, swans, geese, ducks, pigeons, and many other varieties of birds are found. Reptiles and insects are numerous.

The trees of Oregon include—*Rhamnus Purshiana* (bearberry), *Acer circinatum* (vine maple), *A. macrophyllum* (large-leaved maple), *Prunus* (*Cerasus*) *emarginata*, var. *mollis* (wild cherry), *P.* (*C.*) *demissa* (choke-cherry), *Nuttallia cerasiformis* (seam-berry, or squaw-berry), *Cercocarpus ledifolius* (mountain mahogany), *Pyrus rivularis* (Oregon crab-apple), *P. sambucifolia* (mountain ash), *Crataegus Douglasii* (black haw), *C. rivularis*, *Amelanchier canadensis* (service-berry), *Cornus Nuttallii* (dog-wood), *Sambucus glauca* (elder), *Arbutus Menziesii* (laurel, madroño), *Arctostaphylos pungens* (manzanita), *Fraxinus oregana* (Oregon ash), *Umbellularia* (*Oreodaphne*) *californica* (myrtle), *Myrica californica*, *Quercus chrysolepis* (live oak), *Q. densiflora*, *Q. Garryana* (white oak), *Q. Kelloggii* (black oak), *Castanopsis chrysophylla* (chinqnapin), *Betula occidentalis* (birch), *Alnus rhombifolia* (alder), *Salix lasiandra* (willow), *Populus tremuloides* (quaking asp), *P. trichocarpa*, *Taxus brevifolia* (yew), *Juniperus occidentalis* (juniper), *Cupressus* (*Chamæcyparis*) *Lawsoniana* (Port Orford cedar), *C.* (*Chamæcyparis*) *Nutkaensis* (Sitka cedar), *Thuya gigantea*, *Libocedrus decurrens* (thick-barked cedar), *Sequoia sempervirens* (redwood), *Abies concolor*, *A. grandis* (white fir), *A. nobilis*, *A. amabilis*, *A. subalpina*, *A.* (*Pseudotsuga*) *Douglasii*, *A.* (*Tsuga*) *Mertensiana* (hemlock), *A.* (*Tsuga*) *Pattoniana* (mountain hemlock), *A.* (*Picea*) *Engelmanni*, *A.* (*P.*) *Sitchensis*, *Larix Lyallii* (larch), *L. occidentalis* (larch, or tamarack), *Pinus contorta* (black pine, or jack pine), *P. albicaulis*, *P. Lambertiana* (sugar pine), *P. monticola* (silver pine), *P. ponderosa*, *P. tuberculata*.[1]

Agriculture, Manufactures, Commerce.—Wheat is the chief crop for home use and for export. All the smaller cereals are grown and produce largely. Flax is indigenous in southern and eastern Oregon; it is cultivated both for seed and for lint. Maize gives a fair harvest, though the nights are too cool for the best results. Vegetables of all kinds common to the temperate zone flourish, and orchard and garden fruits are sure. One species of clover is indigenous, but all varieties grow and spread rapidly over fields, pastures, and burnt forest lands.

Subjoined are the agricultural statistics for the years specified.

	1850.	1860.	1870.	1880.

Other industries	654	2,157,131	1,999,528	3,958,566
Total of all industries	1080	$6,312,056	$6,954,436	$10,931,232

Oregon has three ports of entry—Astoria on the Columbia, Portland on the Willamette, and Coos Bay on the southern coast. The exports to foreign ports for the twelve months ending 31st July 1882 were $9,970,410; exports to domestic ports, $5,899,738; total exports, $15,870,148; wheat, $6,677,418; flour, $2,853,792; salmon, $2,484,761; wool, $1,488,360; oats, $417,640; lumber, $228,392. The salmon-canning business began in 1866 with a product of 4000 cases, valued at $64,000; the average annual value for the six years 1878-83 exceeded $2,000,000. Between Astoria and the cascades of the Columbia river there are about forty canneries. Over 1500 boats are employed in the fishery.

Railroads and Steamers.—In 1865 there were in Oregon 19 miles of railway open; in 1875, 248; in 1880, 582; on 1st March 1884, 900 miles. Steamers ply twice a week between Portland and San Francisco (670 miles), and at frequent intervals on the Columbia river for 725 miles, on the Willamette 138 miles, and on the Snake river 180 miles.

Government and Finance.—The statutes of Iowa and New York were the models of the provisional government of Oregon, and legislation has continued generally on these lines. The courts consist of a supreme court, with appellate jurisdiction, situated in Salem, the capital, and five circuit or district courts, with county courts and justices' courts in every precinct of city and county. Cities have police courts also. There is a United States district court for Oregon, and a United States circuit court for Oregon with California and Nevada. The State debt in 1880 was $511,376, and local, county, city, and school debt was $377,126. The gross value of all property, as compiled from records in the office of the secretary of state in 1882, was $85,531,716; indebtedness, $22,300,912; exemption, $4,973,058; taxable property, $59,257,746; State tax, $325,917·38; wealth per head, $403·90.

Education.—In 1848 Congress granted to Oregon one-eighteenth of all the public domain for free schools. This area (3,387,520

[1] See *Forest Trees of Oregon*, published by Prof. G. H. Collier.

acres) was received by the State on its admission to the Union for the education of all its youth of both sexes. Congress also granted about twenty-six townships (500,000 acres) for a State university, and 90,000 acres for an agricultural college. A portion of these lands has been sold, and the proceeds have been made an irreducible fund for the objects named. The free-school system has been established in every county and almost every settlement. In Portland and other cities grades have been established from "primary" to "high school." The State university is established at Eugene City, and an agricultural college at Corvallis. This public-school system is supplemented by many corporate academies, seminaries, and colleges, and by parochial and private schools representing different denominations. A school for mutes and one for the blind have been established at Salem by the legislature. Ten institutions report as endowments $290,132, yielding an annual income of $16,030, and thirteen report $35,166 from tuition, and a total annual income of $61,070. The number of children of school age (four to twenty years) is 65,216; enrolled in public schools 37,748, in private schools 5101. Public school expenses for the year ending 1st March 1882 amounted to $338,380; the public schoolhouses numbered 1061, of the value of $684,298. The United States Indian Industrial Training School at Forest Grove, which numbers 146 pupils, taken from schools on the reservation, has become a marked success. Of 119,482 white persons over ten years of age in 1880 only 3·6 per cent. were unable to write.

Charitable and Penal Institutions.—A State asylum for the insane at Salem has over 300 inmates. The State penitentiary is at Salem; the convicts are employed under contractors in various industries, subject to constant watch of officials.

Religion.—The statistics of 1875 report 351 religious organizations of all denominations, with 242 church edifices, 320 clergymen, 14,324 communicants, and 71,630 adherents. The estimated value of church property was $654,000. The rank of the several denominations in respect to numbers is approximately as follows: Methodists, Baptists, Roman Catholics, Presbyterians, Episcopalians, Congregationalists, and five minor sects. The increase in seven years by immigration and other gains has been at least 35 per cent.

The Press.—Oregon has 74 newspapers—72 in English and 2 in German. A weekly newspaper is published in every shire town, and in many of the larger villages. Four daily papers are issued in Portland.

Cities and Chief Towns.—PORTLAND (*q.v.*), on the Willamette, 115 miles from the ocean, is the chief city of the Pacific coast north of San Francisco (population in 1880, 17,577); Astoria is a commercial city of 3000 inhabitants, with large salmon-canning establishments, which do an annual business of over $2,000,000; Oregon City, at the falls of the Willamette, is a flourishing manufacturing town; Salem (the capital), Albany, Corvallis, Eugene City, Roseburg, The Dalles, Pendleton, Union, and Baker City are places of rapidly-growing importance.

Population.—The following statistics show the growth of the State during the last three decades:—

Census.	Males.	Females.	Total.	Density per square mile.
1850	8,278	5,016	13,294	0·1
1860	31,646	20,819	52,465	0·6
1870	53,131	37,792	90,923	0·9
1880	103,381	71,387	174,768	1·8

Of the total population in 1880 17½ per cent. (30,503) were of foreign birth, 9472 being Chinese, 5034 Germans, 1557 Scandinavians, 7913 British, and 3019 British Americans.

History.—Oregon at first included all the United States territory between the Pacific Ocean and the Rocky Mountains north of the 42d parallel, and thus had a total area of over 300,000 square miles. The Greek pilot De Fuca, in the service of Spain, in 1592, Admiral Fonte in 1640, and others had visited and mapped the coast as far as the 55th parallel. In 1792 Captain Robert Gray of Boston, in the ship "Columbia," discovered and ascended the river as far as Gray's Bay, and named the river after his vessel. Oregon was afterwards held by the United States Government to have been included in the sale of "Louisiana" by France in 1803. In 1804-5 Lewis and Clark explored the Columbia to its mouth and reported the great resources of the country. In 1810 Captain Winship, a New Englander, built the first house in Oregon, on the Columbia; and in 1811 John Jacob Astor of New York established a fur-trading post 15 miles from the ocean at Astoria on that river. In 1813, during the war, his agent sold it to the North-Western Fur Company, who called it Fort George. Though restored to the United States after the war, it was held by the company, and in 1821 it passed, with their other possessions, into the hands of the Hudson's Bay Company. The British laid claim to Oregon by virtue of Drake's discovery of the coast in 48° N. lat. in 1558, of Cook's visit to De Fuca Strait in search of a north-west passage in 1778, and of the survey of the coast from 30° to 60° N. lat., by order of the British Admiralty, made by Vancouver (who was with Cook in 1778), to find a north-west passage, and his discovery and ascent of the Columbia to the site of the present city of Vancouver in 1792. A treaty of "joint occupation" was made in 1818 between the United States and Great Britain which left these conflicting claims for future settlement and only served to prolong and increase the disagreement. The British finally offered to compromise on the Columbia. In 1824 some employees of the Hudson's Bay Company set out a few fruit trees and cultivated a garden at Fort George (Astoria). In 1832 Captain Nathaniel Wyeth of Wenham, Massachusetts, established a fishery on Sanvie's Island. In 1834 the Revs. Jason and Daniel Lee and others came to Oregon on Captain Wyeth's second trip, to establish a mission of the Methodist Episcopal Church, east of the Cascade Mountains, but they were persuaded by the superintendent of the Hudson's Bay Company to settle in the Willametto valley. They soon collected some dozens of Indian children near the present site of Salem, and established the "Oregon Manual Labour School." Others came, until, in 1840, their mission families numbered fifty-two adults and twenty children. Their mission closed in 1847, and the families became settlers. In 1835 Rev. Samuel Parker and Dr Marcus Whitman were commissioned to explore and plant a mission in Oregon. Under convoy of the yearly expedition of the American Fur Company, Dr and Mrs Whitman, Rev. H. H. Spalding and Mrs Spalding, and Mr W. H. Gray "crossed the plains" in 1836, travelling 2300 miles from the Missouri line, and began a mission among the Indians of eastern Oregon. These two ladies were the first white women who crossed the Rocky Mountains. The missionaries formed the nuclei of settlements; trappers, adventurers, and western pioneers followed; cattle were secured from California, and in 1842 steps were taken for a government, by a choice of officers. The whites numbered only about 240. Western pioneers having been told that waggons could not be taken to the Columbia, and induced to exchange them at Fort Hall for horses, Dr Whitman, to remove the bar thus put up against immigration, recrossed the plains in the winter of 1842-43. He published his plan to help emigrants through to Oregon with their families and waggons, hastened to Washington to arouse Government officials to retain their hold of Oregon and care for it, and then returned, overtaking nearly 1000 emigrants at the North Platte river. A provisional government was organized that year by the people. More immigrants followed. In 1846 a treaty was concluded between Great Britain and the United States fixing the boundary at 49° N. lat. In 1848 Congress established a Territorial government, and the governor, General Joseph Lane, arrived in March 1849. United States courts were then established. On 28th November 1847, Dr and Mrs Whitman, along with twelve others, were murdered by the Indians. War followed, and again broke out in 1855. Other wars against the Indians occurred in 1877 and 1878, but the tribes have mostly been placed upon reservations, under educational and industrial training. They have become peaceable and partially self-supporting, though paid in annuities for their lands. The Territory was admitted into the Union as a State on 14th February 1859. (T. W. S.—G H A.)

OREL, or ORLOFF, a government of central Russia, bounded by Smolensk, Kaluga, and Tula on the N., and by Voronezh, Kursk, and Tchernigoff on the S., with an area of 18,040 square miles. The surface is an undulating plateau gently sloping towards the west; the highest hills do not reach 900 feet, and none of the valleys are less than 450 feet above the sea. Geologically Orel consists principally of Lower Devonian limestones, marls, and sandstones, covered with Jurassic clays, the last appearing at the surface, however, only as isolated islands, or in the valleys, being concealed for the most part under thick beds of cretaceous chalk, marls, and sands. The Carboniferous limestones and clays (of the so-called Moscow basin) appear in the north-west only at a great depth. The Jurassic clays and marls are covered at several places with a stratum of clay containing good iron-ore, while the Devonian sandstones and limestones are worked for building purposes. The whole is buried under a bed, from 30 to 40 feet thick, of boulder-clay and loess, the last covering extensive areas besides the valleys. The soil—a mixture of "black earth" with clay—is fertile, except in the Desna region, which is covered with sands and tough clays. The principal rivers are the Don, which forms the eastern boundary of the government and has many tributaries, the chief being the Sosna; the Oka, which rises in the district of Orel and receives the navigable Zusha and

many smaller streams; and the Desna, with the Bolva, draining the marshy lowlands in the west. On the Oka, Zusha, Desna, and Bolva there is a brisk traffic in corn, oil, hemp, timber, metal, glass, china, paper, and building-stone. Marshes occupy large areas in the basin of the Desna, as also in several parts of that of the Oka; they are mostly covered with forests, which occupy from 50 to 65 per cent. of the districts of Bryansk, Trubtchevsk, and Karatcheff, while towards the east, in the basin of the Don, wood is so scarce that straw is used for fuel. The climate is moderate, the average yearly temperature at Orel being 41°·2 (14°·8 in January and 67°·0 in July).

The population, 1,596,900 in 1870, and 1,877,100 in 1881, consists almost exclusively of Great Russians belonging to the Greek Church; the Nonconformists are reckoned at about 12,000, the Catholics at 3000, and the Jews at 1000. The chief occupation is agriculture, which is most productive in the east and towards the centre of the government. In 1877 59 per cent. of the province was under crops, the estimated yield being 7,196,000 quarters of corn and 1,212,000 quarters of potatoes. Of the grain not used in the distilleries a large proportion is exported to the Baltic. Hemp and hemp-seed oil are extensively exported from the west to Riga, Liban, and St Petersburg. Tobacco is also cultivated with profit. Cattle-breeding and horse-breeding, though somewhat depressed within the last twenty years, are still in a better condition than in neighbouring governments,—the Orel breeds, both of carriage and of cart horses, being held in estimation throughout Russia. In 1881 there were 500,000 horses, 340,000 cattle, and 790,000 sheep. Bee-culture is widely diffused in the forest districts, as are also the timber-trade and the preparation of tar and pitch. Manufactures are rapidly increasing; in 1879 there were 540 larger industrial establishments, employing 14,130 hands, and producing cast-iron rails, machinery, locomotive engines and railway waggons, glass, hemp-yarn and ropes, leather, timber, soap, tobacco, chemical produce, &c. There are also distilleries and a great many smaller oil-works and flour-mills. Karatcheff and Syevsk are important centres for hemp-carding; Bolkhoff and Elets are the chief centres of the tanning industry; while the districts of Elets, Dmitroff, and partly Mtsensk supply flour and various food-pastes. At Bryansk a Government cannon-foundry employs 700 hands. The so-called "Maltsoff's works" in the district of Bryansk are worthy of mention as an industrial colony comprising several iron, machinery, glass, and rope works, where thousands of peasants find temporary or permanent employment; they have their own technical school, employ engineers of their own training, and have their own narrow-gauge railways and telegraphs, both managed by boys of the technical school. Numerous petty trades are carried on by peasants, along with agriculture. The fairs held in many villages are animated, and have some importance for the cattle trade. Orel is divided into twelve districts, the chief towns of which are Orel (76,700 inhabitants), Bolkhoff (29,020), Bryansk (12,660), Dmitrovsk (6560), Elets (41,450), Karatcheff (11,200), Kromy (3050), Livny (21,170), Maloarkhanghelsk (3920), Mtsensk (14,200), Syevsk (9650), and Trubtchevsk (5170).

In the 9th century the country was inhabited by the Syeveryanes on the Desna and the Vyatichees on the Oka, who both paid tribute to the Khazars. The Syeveryanes recognized the rule of the princes of the Rurik family from 884, and the Vyatichees from the middle of the 10th century; but the two peoples followed different historical lines, the former entering into the Suzdal principality, while the latter fell under the rule of that of Tchernigoff. In the 11th century both had wealthy towns and villages; during the Tartar invasion these were all burned and pillaged, and the whole territory, lying as it did on the two chief lines of the Tartar advance, became a desert, where the Nogays encamped with their herds. With the fall of the Great Horde the western part of the country fell under Lithuanian rule and was the subject of repeated struggles between Lithuania and Moscow. In the 16th century the Russians began to erect new forts or to fortify the old towns, and the territory was rapidly colonized by immigrants from the north. In 1610 the towns of the present government of Orel (then known as the Ukrayna or "border-region") had an active share in the insurrection against Moscow under the pseudo-Demetrius, and suffered much from the civil war which ensued. They continued, however, to be united with the rest of Russia, and in the next century formed a basis for further Russian advance towards the south.

Orel, capital of the above government, lies at the confluence of the Oka with the Orlik, on the great line of railway to the Crimea, 238 miles south-south-west from Moscow. It has railway connexion also with Smolensk and the Baltic ports in the west, and with Saratoff, Tsaritsyn, and Novotcherkassk in the south-east. It was founded in 1566, but developed slowly, and had only a very few houses at the beginning of the last century. The cathedral, begun in 1794, was finished only in 1861. The town now possesses a military gymnasium (corps of cadets), a few secondary schools, a public library, and a theatre; large storehouses for grain and timber, a spacious *gostinoy dvor* with numerous shops, and the offices of the municipal bank are perhaps its best buildings. The manufactures are rapidly increasing; in 1879 the hemp-carding, hemp-spinning, and rope-making industries produced 1,020,000 roubles, the flour-mills about 300,000 roubles, and the aggregate from all the manufactures exceeded 2,000,000 roubles. Orel is one of the chief markets of central Russia for the trade in corn and hemp, as also in hemp-seed oil and tallow, which are shipped down the Oka or sent by rail. Metal wares, tobacco, kaolin, and glass ware are also exported, while salt, groceries, and manufactured goods are imported for distribution throughout the villages of the government, or to be sent to the Don Cossacks. The population, 45,000 in 1875, was 76,700 in 1881.

ORENBURG, a government of south-eastern Russia, bounded on the N. by Ufa and Perm, on the S. and E. by the steppe of the Orenburg Kirghiz, and on the W. by Samara, has an area of 73,890 square miles. Situated at the southern extremity of the Urals and extending to the north-east on their eastern slope, Orenburg consists of a hilly tract bordered on both sides by steppes. The central ridge occasionally reaches an elevation of about 5000 feet; there are several parallel ridges, which, however, nowhere exceed 2600 feet, and gradually sink towards the south. A great variety of geological formations are represented within the government. Diorites and granites enter it from the north and appear at many places from under the Silurian and Devonian deposits. The Carboniferous limestones and sandstones, as also softer Permian, Jurassic, and Cretaceous deposits, have a wide extension in the south and east. Magnetic iron, copper, silver, and lead ores, auriferous sands, and salt from the lakes constitute the mineral wealth of Orenburg, along with its very fertile "black earth," which covers wide areas around the Urals. It is traversed from north to south by the Ural river, which also forms its southern boundary; the chief tributaries are the Sakmara and the Ilek. The upper courses of the Byelaya and the Samara, tributaries of the Kama and the Volga, also lie within the government, as well as the affluents of the Tobol on the eastern slope of the Ural range. Numerous salt lakes occur in the district of Tchelabinsk; but several parts of the flat lands occasionally suffer from want of water. Thirteen per cent. of the surface is under wood. The climate is continental and dry, the average temperature at Orenburg being 37°·4 Fahr. (4°·5 in January, 69°·8 in July). Frosts of −38°, and heats of 98° are not uncommon.

The population (900,550 in 1870) numbered 1,120,700 in 1881. The increase is largely due to immigration, an extensive tract of uncultivated land which formerly belonged to the Bashkirs having recently been purchased by the Government officials and leased to immigrants from the interior of Russia. The inhabitants are mainly Great Russians, Bashkirs (26 per cent.), and Kirghiz (about 5 per cent.). The majority belong to the Greek Church, or are Nonconformists; 27 per cent. are Mohammedans. The chief occupations are agriculture and cattle-breeding. Although only 3·2 per cent. of the area is under crops, grain is both distilled and exported. In 1881 there were in the province 581,000 horses, 441,000 cattle, 850,000 sheep, and 65,000 pigs. Notwithstanding the abundance of iron and copper ore, mining is but little developed. The industrial establishments (distilleries, tanneries, flour-mills, &c.) are few, and their aggregate production in 1879 was only 5,195,000 roubles, employing about 2200 workmen. The export trade in corn, skins, and tallow is of some importance, and the fairs at Orenburg, Troitsk, and Tchelabinsk yield large returns. There are five districts, the chief towns of which are Orenburg (35,600 inhabitants), Orsk (14,350), Tchelabinsk or Tchelaba (9000), Troitsk (8300), and Verkhneuralsk (10,350).

The territory of the Orenburg Cossacks, which extends as a narrow strip up the Ural river, occupies the whole of the government east of the Ural mountains, and joins, by a narrow line of posts, the former line of blockhouses of the Siberian Cossacks, has an area of 35.820 square miles, with a population in 1880 of 290,800 Cossacks and 16,460 peasants; 25,000 were Moslem Bashkirs.

Orenburg, capital of the above government, is situated on the right bank of the Ural river, 933 miles by rail south-east from Moscow. The fortress, which has eleven bastions and a circumference of 6300 yards, has lost its importance since the recent advances of Russia towards the south-east, and is falling into decay. The town, on the other hand, is rapidly increasing, and now includes the former suburbs of Golubinaya and Novaya. The population is 35,600. Orenburg has a military cadet school, two lower military schools, a lyceum, and various primary schools,—one of them for Kirghiz children. The inhabitants are chiefly occupied in agriculture and trade. The manufactures are few, but the trade is steadily increasing; the imports include cotton, silk, furs, wool, cattle, and horses, while cotton and woollen stuffs, cotton yarn, leather, colours, sugar, and grain are exported. Orenburg is connected by rail with Samara on the Volga and with Moscow.

The government of Orenburg was formerly inhabited by the Kirghiz in the south and the Bashkirs in the north. The latter were brought under the rule of Russia in 1557, and the fort of Ufa was erected a few years later in order to protect them against the raids of the Kirghiz. The frequent risings of the Bashkirs and the continuous attacks of the Kirghiz led the Russian Government in the 18th century to erect a line of forts and blockhouses on the Ural and Sakmara rivers, which was afterwards extended south-westwards towards the Caspian, and eastwards towards Omsk. The central point of these military lines was the fort of Orenburg, originally founded at the confluence of the Or with the Ural (now Orsk), and afterwards removed (in 1740) 120 miles lower down the Ural river to its present site. In 1773 it was besieged by Pugatchoff, the leader of the great revolt of the peasantry, supported by the Bashkirs. The government of Orenburg was created in 1774, embracing a wide territory which reached to the Volga, to the Caspian, and to Perm, the limits to the eastward being undefined. In 1865 this was divided into two governments,—Ufa in the north and Orenburg in the south. The steppe of the Kirghiz, which extends south of the Ural river towards the Caspian and the Sea of Aral, continued under the jurisdiction of the governor-general of Orenburg. Recently the steppe of the Orenburg Kirghiz has been incorporated with the newly-created provinces of Turgay and Uralsk; and the territory of the Orenburg Cossacks, formerly independent, has been brought within the government of Orenburg, and subdivided into districts.

ORENSE, an inland province of Spain, is bounded on the N. by Pontevedra and Lugo, on the E. by Leon and Zamora, on the S. by Portugal (Traz oz Montes), and on the W. by Portugal (Entre Douro e Minho) and Pontevedra, and has an area of 2738 square miles. Its general character is mountainous, and its products are those common to all GALICIA (q.v.), of which historical province it formed a part. The principal rivers are the Minho and the Sil. The population in 1877 was 388,835; only one town (Orense) had a population exceeding 10,000.

Orense, capital of the above province, and the see of a bishop, suffragan to Santiago, stands on the western slope of Montealegre, on the left bank of the Minho. The river is here crossed by a bridge—one of the most remarkable in Spain—of seven arches, 1319 feet in length, and at its highest point 135 feet above the bed of the river, built by Bishop Lorenzo in 1230 and repaired about the middle of the 15th century. The principal feature of the town is the Gothic cathedral, also dating from Bishop Lorenzo's time (1230); it is a comparatively small and unimportant building, but has a miraculous image, "El Santo Cristo," of wide celebrity in Spain, which was brought from Cape Finisterre in 1330. The three warm springs to the west of the town, known as Las Burgas, attract a considerable number of summer visitors; the waters are similar to those of Carlsbad. The trade and manufactures of the place are unimportant. Orense—the *Aquæ Originis*, or perhaps *Salientis*, of the Romans—in 1877 had a population, within the ayuntamiento, of 12,586.

ORESTES, son of Agamemnon and Clytæmnestra. According to the legend in Homer, he was absent from Mycenæ when his father returned from the Trojan War. and was murdered by Ægisthus. Eight years later Orestes returned, and revenged his father's death by slaying his mother and her paramour. Pindar mentions that his nurse saved him and conveyed him out of the country when Clytæmnestra wished to kill him. The tale is told much more fully and with many variations in the tragedians. He was preserved by his sister Electra, and conveyed to Phanote on Mount Parnassus, where king Strophius took charge of him. In his twentieth year he was ordered by the oracle to return home and revenge his father's death. According to Æschylus, he met his sister Electra before the tomb of Agamemnon, whither both had gone to perform rites to the dead; a recognition takes place, and they arrange how Orestes shall accomplish his revenge. Orestes, after the deed, goes mad, and is pursued by the Erinnyes, whose duty it is to punish any violation of the ties of family piety. He takes refuge in the temple at Delphi; but, though Apollo had ordered him to do the deed, he is powerless to protect his suppliant from the consequences. At last Athena receives him on the acropolis of Athens and arranges a formal trial of the case before twelve Attic judges. The Erinnyes demand their victim; he pleads the orders of Apollo; the votes of the judges are equally divided, and Athena gives her casting vote for acquittal. The Erinnyes are propitiated by a new ritual, in which they are worshipped as Eumenides (the Kindly), and Orestes dedicates an altar to Athena Areia. Such is the account in which authorities generally agree, but Euripides introduces a different series of adventures after Orestes has taken refuge at Delphi. Apollo orders him to go to Tauris, carry off the statue of Artemis which had fallen from heaven, and bring it to Athens. He repairs to Tauris with Pylades, and the pair are at once imprisoned by the people, among whom the custom is to sacrifice all strangers to Artemis. The priestess of Artemis, whose duty it is to perform the sacrifice, is Iphigeneia, the daughter of Agamemnon, who had been transported hither by the goddess when her father was about to offer her (see IPHIGENEIA). She offers to release Orestes if he will carry home a letter from her to Greece; he refuses to go, but bids Pylades take the letter while he himself will stay and be slain. After a conflict of mutual affection, Pylades at last yields, but the letter brings about a recognition between brother and sister, and all three escape together, carrying with them the image of Artemis.

Orestes appears also as a central figure in the legends of many other places. In Cappadocia he introduced the worship of Artemis Tauropolos at Comana and Castabala. Near Gythium in Laconia was a stone called Zeus Cappotas; here the madness left Orestes. In Trœzen there was before the temple of Artemis a stone on which Orestes was purified, and a hut in front of the temple of Apollo Thearius in which he stayed till the purification was accomplished. Seven stadia from Megalopolis, on the left of the road to Messene, was a shrine of the Maniæ, i.e., the Erinnyes. Immediately beyond it was a tumulus, on the summit of which was an upright stone like a finger, [illegible], where Orestes bit off his own finger in his madness. Beyond the mound was another shrine of the Erinnyes, worshipped now as Eumenides in association with the Charites (see GRACES). Here the Erinnyes, who had hitherto appeared black to Orestes, appeared white to him, and the madness left him. Then he cut off his hair as an offering at a place [illegible]. The name of the tumulus is clearly connected with the belief still frequently occurring that a hand appears out of the tomb of any person who has murdered a mother or been murdered by her. The tumulus itself was obviously one of those graves, which were especially common in Lydia, a tumulus with a pillar on the apex; such tumuli were found in Laconia, where, as Athenæus says, they were called "the graves of the Phrygians who came with Pelops."

In these legends it is apparent that Orestes is the guilt-laden mortal who is purified from his sin by the grace of the gods; his purification is a type of the merciful justice which the gods intend should be shown to all persons whose crime is mitigated by extenuating circumstances. These legends belong to an age when higher ideas of law and of social duty were being established; the implacable blood-feud of primitive society gives place to a fair trial of the culprit, and in Athens, when the votes of the judges are evenly divided, mercy prevails. In the religion of Delphi similar ideas underlie the ancient festival Septerion: in it Apollo himself is the murderer, and his example sets forth to mankind the method of purification which heaven opens to such sinners, if they are not entirely and wilfully guilty. Orestes is not a figure of the Apollo religion, but is clearly connected with the cultus of the Erinnyes; and his relation to these goddesses, and the intention of the myth, are very plain in the Megalopolitan legend above mentioned. The Trœzenian legend has no appearance of being really ancient, just as the tales that connect Orestes with the district Orestea in Arcadia, or Orestias in Epirus, are obviously fictions of a later time. On the other hand, the Orestes of Tauric and Cappadocian legend is a different person, connected with the spread of Artemis-worship; it is not improbable that a similarity of name caused the identification of two heroes belonging respectively to the cultus of Artemis and of the Erinnyes.

Orestes had an historic part assigned to him as Greek mythology became systematized. Phocian auxiliaries restored him to the throne of his father, and, according to Hellanicus, he began the Æolic migration to Asia Minor. He was buried on the road from Tegea to Thyrea, and Herodotus (ii. 67) tells a quaint story of the manner in which the Spartans discovered his bones and, in obedience to an oracle, carried them to Sparta.

ORFA. See Edessa, vol. vii. p. 652.

ORFILA, Mathieu Joseph Bonaventure (1787-1853), the founder of modern toxicology, and one of the most eminent of the French school of medicine during its brightest period, was by birth a Spaniard, having been born at Mahon in Minorca on 24th April 1787. An island merchant's son looked naturally first to the sea for a profession; but a voyage at the age of fifteen to Sardinia, Sicily, and Egypt did not prove satisfactory. He next took to medicine, which he studied at the universities of Valencia and Barcelona with so great applause that the local authorities of the latter city granted him a pension to enable him to follow his studies at Madrid and Paris, preparatory to appointing him professor. He had scarcely settled for that purpose in Paris when the outbreak of the Spanish war, in 1807, threatened destruction to his prospects. But he had the good fortune to find a parent in a merchant uncle at Marseilles, and a patron in the good and great Vauquelin the chemist, who braved the wrath of Napoleon against the Spaniards, claimed him as his pupil, guaranteed his conduct, and saved him from expulsion from Paris. Four years afterwards he graduated, and immediately became a private lecturer on chemistry in the French capital. In 1819 he was appointed professor of medical jurisprudence, and four years later he succeeded Vauquelin as professor of chemistry in the faculty of medicine at Paris. In 1830 he was nominated dean of that faculty, a high medical honour in France. Under the Orleans dynasty, honours were lavishly showered upon him: he became successively member of the council of education of France, member of the general council of the department of the Seine, and commander of the Legion of Honour. The republic of 1848 put an end to these adventitious distinctions; and chagrin at the treatment he experienced at the hands of the Governments which succeeded that of Louis Philippe is supposed to have shortened his life. He died, after a short illness, in March 1853.

Orfila's chief publications are four in number:—*On General Toxicology* (1814), *A Treatise on Chemistry* (1817), *On Medical Jurisprudence* (1823), and *Medico-legal Exhumations* (1836); but he also wrote many valuable papers, chiefly on subjects connected with medical jurisprudence. His fame will rest mainly on the first-named (*Traité de Toxicologie Générale*), published when he was only in his twenty-seventh year. It is a vast mine of experimental observation on the symptoms of poisoning of all kinds, on the appearances which poisons leave in the dead body, on their physiological action, and on the means of detecting them. Few branches of science, so important in their bearings on every-day life and so difficult of investigation, can be said to have been created and raised at once to a state of high advancement by the labours of a single man.

ORFORD, Earls of. See Walpole.

ORGAN. The notes of the organ are produced by *pipes*, which are blown by air under pressure, technically called *wind*. Pipes differ from one another in two principal ways—(1) in *pitch*, (2) in *quality* of tone. (1) Consider first a series of pipes producing notes of similar quality, but differing in pitch. Such a series is called a *stop*. Stops. Each stop of the organ is in effect a musical instrument in itself. (2) The pipes of different stops differ, musically speaking, in their quality of tone, as well as sometimes in their pitch. Physically, they differ in shape and general arrangement. The sounding of the pipes is determined by the use of *keys*, some of which are played by the hands, some by the feet. A complete stop possesses a pipe for every key of some one row of manuals or pedals. If one stop alone is caused to sound, the effect is that of performance on a single instrument. There are such things as incomplete stops, which do not extend over a whole row of keys; and also there are stops which have more than one pipe to each key. Every stop is provided with mechanism by means of which the wind can be cut off from its pipes, so that they cannot sound even when the keys are pressed. This mechanism is made to terminate in a *handle*, which is commonly spoken of as the *stop*. When the handle is pushed in, the stop does not sound; when the handle is pulled out, the stop sounds if the keys are pressed. An organ may contain from one to four *manuals* or *keyboards* and one set of pedals. There are exceptional instruments having five manuals, and also some having two sets of pedals. The usual compass of the manuals is four and a Compass. half octaves, from C to g''' inclusive. The compass of the pedal is two and a half octaves, from C to f. This represents the pitch in which the notes of the pedal are written; but the pedal generally possesses stops sounding one octave lower than the written note, and in some cases stops sounding two octaves below the written note. Each manual or pedal has as a rule one *soundboard*, on which Sound-board, &c. all its pipes are placed. Underneath the soundboard is the *windchest*, by which the wind is conveyed from the bellows, through the soundboard, to the pipes. In large organs there may be two or more soundboards for one manual or pedal. The windchest contains the mechanism of valves by which the keys control the admission of wind to the soundboard. The soundboard contains the grooves which receive the wind from the valves, and the slides by which the handles of the stops control the transmission of the wind through the soundboard to the pipes of the different stops.

The *grooves* of the soundboard are spaces left between wooden bars glued on to the *table* of the soundboard. There is usually one groove for every key. The grooves of the bass notes, which have to supply wind for large pipes, are broader than those of the treble. The bass bars are also thicker than those of the treble, that they may the better support the great weight which rests on the bass portion of the soundboard. The table

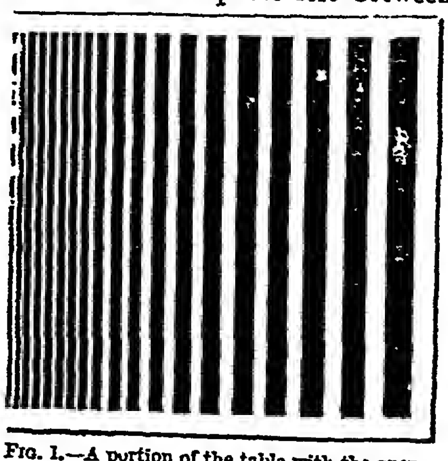

Fig. 1.—A portion of the table with the open grooves seen from below.

forms the top of the grooves. The grooves are generally closed below with leather, except the opening left in each, which is closed by the key-valve or *pallet*.

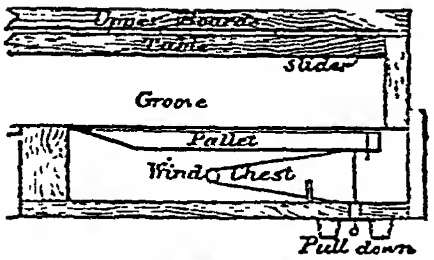

FIG. 2.—A section of a groove, with the table, windchest, and pallet.

The sliders are connected with the draw-stops or stop-handles, which are covered in with stout *upper boards*, on which the pipes stand. The stop-handles are pulled out, and holes are then bored straight down through the upper boards, sliders, and table to admit the wind from the grooves to the pipes. When the sliders are shifted by pushing in the handles, the holes no longer correspond, and the pipes are silenced.

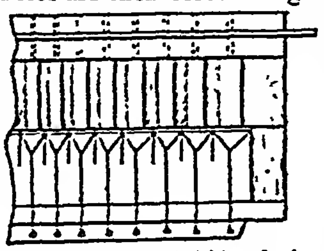

FIG. 3.—A section at right angles to fig. 2.

Pipes are divided first into *flue-pipes* and *reed-pipes*. Flue-pipes are blown by a wind mouthpiece characteristic of the organ, while in reed-pipes the wind acts on a metal tongue vibrating on a reed, and the motion of the tongue determines the speech of the pipe.

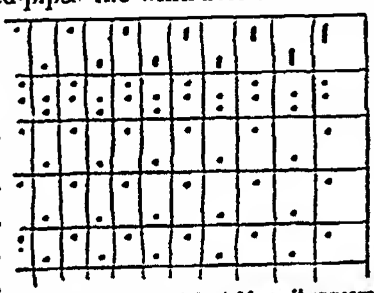

FIG. 4.—A portion of the table as it appears from above, with the places for the sliders of the stops; the small circles show the holes for the wind.

Pipes are made either of wood or of metal. Wood flue-pipes are generally of the form of a rectangular parallelepiped, metal flue-pipes of a cylindrical shape. Reed-pipes are conical or pyramidal, and widen towards the top. Some flue-pipes are made with stopped ends; these as a rule sound a note about an octave lower than the corresponding open pipes of the same length. Such are the stopped diapason, bourdon, and stopped flute.

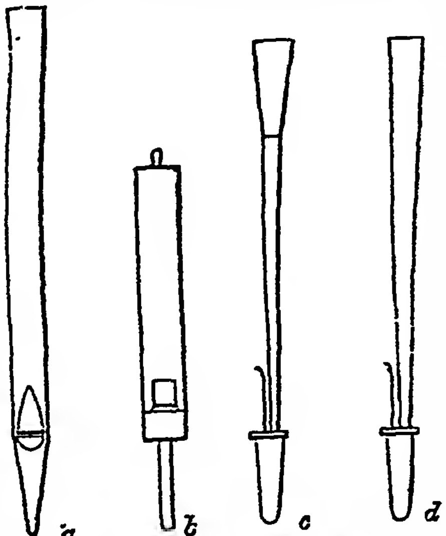

FIG. 5.—*a*, an open diapason; *b*, a stopped diapason; *c*, an oboe; and *d*, a trumpet,—*c* and *d* being forms of reed-pipes.

The general elementary theory of the resonance of a pipe is tolerably simple. The effective length of the pipe is determined by measuring from the upper lip to the open end in open pipes, and from the upper lip to the stopper and back again in stopped pipes. To this is added an allowance for the effect of each opening, since the condition of perfect freedom from constraint does not subsist at the opening itself. The corrected length is traversed twice (backwards and forwards) by sound, in the time of one vibration of the resultant note. This describes in a rough and general manner the way in which any disturbance gives rise to the note of the pipe; but the theory of the mouthpieces is a much more difficult matter, into which we cannot here enter.

In reed-pipes which are simply conical the resonance of the body is nearly the same as that of an open pipe of the same length. Where the form is irregular no simple rule can be given. But the resonance of the body of the pipe is generally the same as the note produced. The tongue of a reed-pipe alternately opens and closes the aperture of the reed. In this way it admits pulses of wind to the body of the pipe; these, if they recur at the proper intervals, maintain its vibration, which takes place when the note produced corresponds to the resonance of the pipe. The reed itself has its vibrating length determined by a wire which presses against it. The free end of this wire is touched with the tuning tool until a satisfactory note is produced.

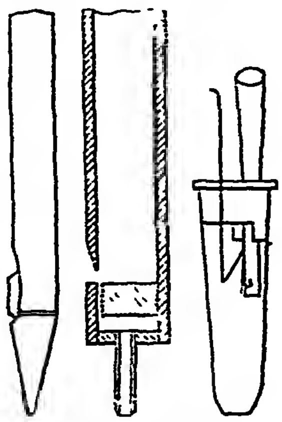

FIG. 6.—Mouthpieces in somewhat greater detail.

The pitch of the different stops is commonly denoted by the conventional approximate length of the pipe sounded by C, the lowest key of the manual. Even in incomplete stops which have no bass, the length of the pipe which C would have if the stop were extended down serves to indicate the pitch. Foot-length, pitch, &c.

The conventional length of the C-pipe for stops having the normal pitch of the keys is 8 feet; a pipe having twice this length sounds the octave below, a pipe having half that length the octave above, and so on. Thus stops which sound the octave below the normal pitch of the keys are spoken of as 16-foot stops. Even where the pipes are stopped so that the actual length is only 8 feet, they are spoken of as having "16-foot tone." Similarly 32-foot stops sound two octaves below the normal pitch of the keys. But if these notes are produced by stopped pipes, whose actual length is only 16 feet, they are spoken of as having "32-foot tone." Sixteen-foot and 32-foot stops are specially characteristic of the pedal, where the names also signify the length of the open pipe which would sound the note actually produced by the lowest C. In old organs, where the modern compass was not adopted, it was not unusual to find stops spoken of as of 12 feet or of 24 feet. In these cases the lowest note was frequently F. Old English organs, however, more often had G for their lowest note. The designation of the stops in these cases had become rather anomalous, and need not be entered into. Of stops higher than the normal pitch of the keys, the octave is denoted by 4 feet if made with open pipes, 4-foot tone if stopped; the twelfth is commonly spoken of as $2\frac{2}{3}$, the fifteenth or double octave as 2 feet. Higher-sounding stops are occasionally used, but these generally form part of "mixtures," and the foot-lengths of the separate ranks are not usually given.

The true or accurate lengths of the pipes vary within considerable limits. The base of the scales (dimensions) varies according to the standard of pitch, and the voicing and the complicated natural laws of pipes produce other deviations from simple relations, so that the conventional dimensions can only be regarded as a simple means of classifying the stops according to their pitch-relations. For this purpose they are essential; they are continually appealed to in discussion and description; and they are almost invariably marked on the stop-handles in all countries, so that a moderate knowledge of foreign nomenclatures, combined with the habit of seizing the meaning

of the figures such as 16, 8, 4, on the stop-handles, will frequently suffice as a key to the complexities of a foreign organ.

Manuals. Each of the manuals, or rows of keys, of an organ constitutes a separate organ, which is more or less complete in itself. The names of the different manuals or organs are *great organ*, *swell organ*, *choir organ*, and *solo organ*. The fifth manual, where it occurs, is the *echo organ*. The above is the usual order in point of development and frequency of occurrence, although the solo is sometimes preferred to the choir organ. The great organ is in a certain sense the principal department of the organ. It may be regarded as formed by a completely developed series of those fundamental stops which constitute the solid basis of the tone of the instrument. If an instrument be constructed with only a single manual this necessarily assumes, in general, the characteristics of a great organ. The great organ is called "grande orgue" in French, and first manual or "hauptwerk" in German.

It is proposed to describe the principal organ-stops under the heads of the manuals to which they belong. The enumeration will not be exhaustive, but will include all the usual types.

Great organ. The great organ commences generally with stops of 16-foot length or tone in large instruments. In some cases a 32-foot sounding stop is introduced, but this cannot be said to be a proper characteristic of the great organ. The foundation tone is of 8 feet; the stops of higher pitch serve to add brilliancy; those of 16 feet, which sound the octave below the normal pitch, serve to add gravity and weight to the tone. Sixteen-foot stops are commonly spoken of as "doubles," their conventional length being twice that of stops of normal pitch.

The 16-foot stops are the 16 double open diapason, and the 16 bourdon or double stopped diapason, to which, in very large instruments, there may be added a 16 double trumpet. The double open diapason on the great organ consists usually of metal pipes, having moderate "scale" or transverse dimensions. These are of the same general character as the pipes of the ordinary open diapason, though they are made somewhat less powerful. In the better instruments of the second class as to size this stop alone would probably be regarded as representing suitably and sufficiently the class of doubles on the great organ. It gives great body to the general tone, and appears decidedly preferable to the bourdon, which frequently takes its place. The 16 double dulciana may be regarded as a variation of the double open diapason. It is sometimes used where the full effect of a double open is not considered desirable. It possesses the light and not full tone of the dulciana. It does not appear to be peculiarly suitable for the purposes of a double.

The 16 bourdon or double stopped diapason, when used on the great organ, is made of rather small scale and light tone. It gives great body to a large great organ, and affords interesting combinations with other stops, such as the 4-foot flute. It is used either alone in smaller organs of the second class or in addition to a double open in larger instruments. The notes are produced from wooden pipes of rectangular section, stopped at the end, and having half the conventional length.

The 16 double trumpet is a trumpet (large reed stop) sounding the octave below the normal pitch. It is used generally in instruments of the largest size, but is somewhat more common in Germany. It is useful in giving a massive character to the tone of the full great organ, which is otherwise apt to become disagreeable on account of the great development of stops of a piercing character. If, however, the double trumpet is rough in tone, it is apt to communicate to the whole a corresponding impression. The judicious balancing of such elements as the double trumpet and the piercing stops such as mixtures is one of the principal features of a good German great organ.

Great organ 8 feet. We now proceed to the 8-foot stops (the reeds come at the end according to ordinary usage). An ordinary great organ may contain 8 stopped diapason, 8 open diapason (one or more), 8 gamba, and 8 hohlflöte. The 8 stopped diapason on the great organ is usually of wood, of moderate scale, and some considerable fulness of tone. The actual lengths are about half the conventional lengths. These pipes are sometimes made of metal. Few stops admit of more variety and individuality in their quality of tone than the stopped diapason; but too frequently the great organ stopped diapason fails to attract attention on its merits, being regarded simply as an inconsiderable portion of the foundation tone.

If there is any one stop which in itself represents the organ as a whole it is the open diapason. The pipes of this stop are the typical metal pipes which have always been characteristic of the appearance of the organ. A single open diapason stop is capable of being used as an organ of sufficient power for many purposes, though of course without variety. The pipes of this stop are called "principal" in German, this appellation apparently corresponding to the fact that they are the true and original organ-pipes. The English appellation of "diapason" has been taken to mean that these are the normal pipes which run through the whole compass. This, however, does not appear to be the actual derivation of the term; originally it is technically applied to the organ-builder's rule, which gives the dimensions of pipes; and it appears that the application to the stop followed on this meaning.

The scales, character, and voicing of the open diapason vary with fashion, and are different in different countries. We may distinguish three principal types. The old English diapasons of the days before the introduction of pedal organs into England were characterized by a rich sweet tone, and were not very powerful. They were generally voiced on a light wind, having a pressure equivalent to that of a column of water of from 2 to $2\frac{1}{2}$ inches. The scale was in some cases very large, as in Green's two open diapasons in the old organ at St George's, Windsor; in these the wind was light and the tone very soft. In other cases the scale was smaller and the voicing bolder, as in Father Smith's original diapasons in St Paul's Cathedral. But on the whole the old English diapasons presented a lovely quality of tone. English travellers of those days, accustomed to these diapasons, usually found foreign organs harsh, noisy, and uninteresting. And there are many still in England who, while recognizing the necessity of a firmer diapason tone in view of the introduction of the heavy pedal bass, and the corresponding strengthening of the upper departments of the organ tone, lament the disappearance of the old diapason tone. However, it is possible with care to obtain diapasons presenting the sweet characteristics of the old English tone, combined with sufficient fulness and power to form a sound general foundation. And there can be no doubt that this should be one of the chief points to be kept in view in organ design.

The German diapason was of an entirely different character from the English. The heavy bass of the pedals has been an essential characteristic of the German organ for at least two or three centuries, or, as it is said, for four. The development of the piercing stops of high pitch was equally general. Thus foundation work of comparatively great power was required to maintain the balance of tone; the ordinary German diapason was very loud, and we may almost say coarse, in its tone when compared with the old English diapason. The German

stop was voiced as a rule on from 3½ to 4 inches of wind, not quite twice the pressure used in England.

The French diapason is a modern variety. It may be described as presenting rather the characteristics of a loud gamba than of a diapason. In other words, the tone tends towards a certain quality which may be described as "tinny" or metallic, or as approaching to that of a string instrument of rather coarse character. Some modern English builders appear to aim at the same model, and not without success.

The tone of a diapason must be strong enough to assert itself. It is the foundation of the whole organ tone. It is the voicer's business to satisfy this condition in conjunction with the requirement that the tone shall be full and of agreeable quality.

The 8 spitzflöte may be regarded as a variety of open diapason. The pipes taper slightly towards the top, and the quality is slightly stringy. This stop was much used at one time in place of a second open diapason. But it appears better that, where two open diapasons are desirable, they should both be of full diapason quality, though possibly of different strengths and dimensions. The admixture of stringy qualities of tone with the diapasons is always to be deprecated.

The 8 gamba was originally an imitation of the viola dá gamba, a sort of violoncello. When made of a light quality of tone it is a pleasing stop; but its use in the great organ instead of a second open diapason is greatly to be deprecated for the reasons just stated. It is frequently found that, where a gamba is provided on the great organ, it is necessary to remove it from the compositions (mechanical arrangements for pulling out the stop-handles in different combinations), as the tone does not blend.

The 8 hohlflöte is an open flute, usually of wood, and of small scale. If made to a moderate scale and fully voiced it possesses a full pleasant tone, which is a useful support to the foundation tone of the great organ. The 8 clarabella differs from the hohlflöte in being usually of rather large scale, and having the open pipes only in the treble. In old organs a separate bass was generally provided; now it is more usual to supply the stop with a stopped bass. The dulciana and keraulophon, though sometimes found on the great organ, are regarded as more appropriately placed elsewhere.

The 4-foot stops of the great organ comprise the 4 principal and the 4 flute. The 4 principal is the octave of the open diapason, generally of somewhat reduced scale and light but bright quality of tone. The use of the word "principal" in connexion with this stop is purely English, and is said to be connected with the use made of it as the standard of tuning for the whole organ. The Germans and French both designate this stop as "octave."

Of the 4 flute there are several varieties,—open, stopped, wood, metal, and harmonic. The harmonic flute has open metal pipes of double the conventional length, which speak their octave. This is determined partly by the voicing, partly by making a small hole about the middle of the length, which determines the motion as that of the two separate lengths between which the hole lies. Harmonic flutes have a sweet but full and powerful tone. Other flutes are generally rather light, except the waldflöte, which is a powerful stop of a somewhat hooting quality.

The great organ flute is frequently used to give brilliancy to light combinations. Thus it may be used with the stopped diapason alone, or with the 16 bourdon alone, or with any of these and either or both of the open diapasons. Where the diapasons are scarcely strong enough to assert themselves in accompaniment, it is a very common practice to put the 4 flute into the diapason composition. If any such use is made of the flute it is desirable that it should not be too strong; but its habitual use to give point to the diapasons is in every way to be deprecated. If the diapasons are not strong enough, let them be altered; but that the diapasons of any organ should never be heard without the accompaniment of a 4 flute is a barbarism.

The ordinary use of the 4-foot stops is to add a degree of loudness to the diapasons. This is accompanied with a certain measure of keenness, which may become disagreeable if the 4-foot tone is disproportionately strong. The ordinary practice is to use the 4-foot tone very freely.

The 2⅔ twelfth stop sounds fiddle *g* on the C key. It is composed of diapason pipes, rather small and gently voiced. Its use is said to be to thicken the tone, which it certainly does. But how far the particular effect produced is desirable is another question. It is generally necessary that this stop should be accompanied by the fifteenth or other octave sounding stop of higher pitch. But in some cases the twelfth can be used with notes of lower pitch only. One such combination is—twelfth, full-toned 8-foot harmonic flute, soft reed in 16-foot pitch. This combination is sometimes used in single notes for solo purposes. The sound of the twelfth appears to be masked or absorbed by the volume of tone of lower pitch. These combinations require careful handling, as the effect of the twelfth is offensive if it remains distinctly perceptible. Great organ twelfth.

The 2 fifteenth, or superoctave, of the great organ consists of diapason pipes sounding notes two octaves above the normal pitch of the keys. The 2 piccolo is a flutey stop of less power, having the same pitch. The 2-foot tone is commonly used as giving a degree of loudness to the great organ beyond that obtainable with the 4-foot tone.

The modern great organ fifteenth is generally a very powerful stop, and requires great caution in its use in organs of moderate size, or in limited spaces. The old English high pitched stops had little power, and their brilliancy was capable of pleasing without offence. The modern great organ up to fifteenth can only be heard with comfort in very large spaces. Under such suitable circumstances the fifteenth is capable of giving to the whole tone a ringing or silvery character, which lends itself specially to contrast with the tone of reeds. This peculiar keen tone, however, requires for its full development the mixtures.

Mixture, sesquialtera, furniture, cymbel, scharf, cornet, are various names applied to a description of stop which possesses several ranks, or several pipes to each note. The pipes of each note sound a chord, which is generally composed of concordant notes of the harmonic series whose fundamental is the proper note of the key. Modern mixtures generally consist of fifths and octaves. Their composition is not the same throughout the whole range of the keyboard. A three-rank mixture may consist of the following (the numbers signify intervals, reckoned along the scale)—

C — c tenor,	15 — 19 — 22
c♯ to top	8 — 12 — 15.

For a somewhat larger full mixture this may be modified as follows—

C — c (middle)	15 — 19 — 22
c♯ to top	1 — 8 — 12 — 15.

A sharp mixture suitable for a large instrument may be as follows—

Five Ranks.

C — c	15 — 19 — 22 — 26 — 29
c♯ — f♯	8 — 12 — 15 — 19 — 22
g — c	1 — 8 — 12 — 15 — 19
c♯ to top	1 — 5 — 8 — 12 — 15

The last two compositions are given by Hopkins in his great treatise on the organ.

The early mixtures generally included the tierce (17th, or two octaves and a third). The German practice was to unite this with a twelfth, carrying the combination 12-17 throughout the keyboard under the name of sesquialtera. It is agreed that there is no direct derivation of this use from the word, and that the name should be sexta. The combination is, however, not now usually provided. The old English sesquialtera was ordinarily simply a form of mixture, as was the furniture. The mounted cornet consisted usually of five ranks—

1—8—12—15—17.

It extended from middle *c* upwards. The pipes were raised on a small soundboard of their own; they were of very large scale and horn-like tone. The stop was used for reinforcing a melody. It is now obsolete.

The question of the employment and composition of mixtures is of the greatest importance with respect to the good effect of the full organ proper, *i.e.*, without reeds. With reference to the whole question of keen-toned stops it may be laid down that their free employment in the great organ does not produce a good effect unless the organ is situated in a very large space. If this is the case, properly proportioned mixtures are capable of giving to the tone of the full diapason work a character which is brilliant without being overpowering. The contrast between this class of tone and that afforded by the reeds is one of the most charming and legitimate effects within the range of the instrument.

Great organ reeds.

We now pass to the reeds. The 16-foot trumpet has been already alluded to, and there remain 8 trumpet and 4 clarion or octave trumpet. These are both stops of great power. The best trumpets possess also richness and smoothness of tone. Stops of this class can be used with the diapasons only, producing what may be described as a rich-toned blare of moderate strength. The more usual employment of the reeds is in connexion with the entire great organ, the whole forming the ordinary fortissimo of the instrument.

Swell organ.

The second department of the English organ is the swell organ. The whole of the swell pipes are enclosed in a box, faced on one or more sides with a set of balanced shutters. When these are closed the tone is almost completely muffled. When the shutters are opened, by means of a pedal usually, the sound bursts out. In order that the use of the swell may be effective, it is necessary that the shutters should close tightly, and that there should be a sufficient volume of tone to produce an effect when they are opened. The swell is of entirely English origin; it has been introduced in Germany to a very small extent, but more widely in France. It is usually called "recitatif" on the Continent. The chief characteristic of the swell is the rich and powerful volume of reed-tone of a peculiar character which it contains. But other stops are also of importance. We consider them in order. The 16 bourdon, small scale, is very commonly used in swells. It assists in giving body to the tone. It occupies, however, a large space within the swell box; and where the choice between it and a 16-foot reed has to be made there can be no doubt that the reed should be preferred, as it contributes so much more to the development of the characteristic swell tone. The 16 contra fagotto and the 16 bass oboe are two alternative forms of 16-foot reed. The first is the more powerful of the two. Either of these stops imparts great richness to the tone of the other swell reeds, giving specially to the bass the peculiar quality which suggests great power.

The 8-foot diapason work is principally valuable for the soft effects obtained from it. The diapasons are voiced less loudly than for the great organ; and within the shutters they sound very soft indeed. The dulciana is the softest stop generally available; and either this or some similar stop is introduced into the swell for the purpose of obtaining effects of the most extreme softness. Space within the swell box has generally to be economized. The complete bass of the open diapason or dulciana requires an 8-foot swell box, whereas even a 16-foot reed can be bent round so as to go within a smaller box if necessary. The open diapason and the dulciana are therefore often cut short at tenor *c*, and completed, if desired, with stopped pipes. The 4 principal and the 4 flute stops are similar to the corresponding stops in the great organ, but are somewhat lighter in tone. As in the case of the great diapasons and the 4-foot flute, it sometimes happens that the first reed combination (oboe) is not strong enough. Then the principal is sometimes put into its composition. This almost invariably spoils the effect entirely.

The 2 fifteenth and mixtures are much more pleasing in the swell than in the great organ. The shutters tone them down, so that they cannot easily become offensive. Added to the reeds, they give a peculiar brilliancy to the full swell. But perhaps their most pleasing use is when all the diapason work of the swell is used alone, and as a contrast to the reeds.

The usual reeds are as follows, besides the doubles already mentioned:—8 oboe, 8 cornopean, 8 trumpet, and 4 clarion (octave trumpet). The oboe (hautboy) is a conventional imitation of the orchestral instrument. It is a stop of delicate tone, and perhaps is at its best in solo passages, softly accompanied on another manual. The cornopean has a powerful horn-like tone. It is the stop which, more than any other, gives to the English swell its peculiar character. The trumpet is used in addition to the cornopean in large instruments. The clarion serves to add brightness and point to the whole.

Choir organ.

The third department is the choir organ. The 8-foot work may contain 8 stopped diapason, 8 open diapason, 8 gamba, 8 keraulophon, and 8 hohlflöte.

As a rule no open diapason is provided for choir organs, unless they are larger than usual; but a small open is most useful as a means of obtaining a better balance than usual against the other manuals. The stopped diapason is generally made to contrast in some way with that on the great organ. The hohlflöte, or its representative, is generally a lighter stop than what would be put on the great organ. The gamba is better placed in the choir organ than in the great or the swell. Such stops as the gamba and the keraulophon are frequently placed in the swell with the idea of adding to the reediness of the tone. But this is fallacious. Their tone is not strong enough to assert itself through the shutters, and their peculiar character is therefore lost. On the choir organ, on the other hand, the sort of strength required is just about what they possess, and they show to advantage. The keraulophon is a stop invented by Gray and Davison, and has been widely adopted for many years. It has a hole made in each pipe near the top, and gives a peculiar tone very well described by its name (horn-flute). Though not very like the gamba, its tone is so far of the same type of quality that the two stops would hardly be used together. It is generally the case that similar stops of exceptional characters do not combine well, whereas stops of opposed qualities do combine well. Thus a gamba and a keraulophon would not combine well, whereas either of them forms an excellent combination with a stopped diapason or a hohlflöte.

The 4 principal is sometimes very useful. A light combination on the choir, with excess of 4-foot tone, may often be advantageously contrasted with the more full and solid tone of the great diapasons, or with other attainable effects. The 4 flute is constantly used. The 2 piccolo is frequently found on the choir organ, but is not particularly useful.

In organs which have no solo manual there is usually a clarionet (cremona, cromorne, or krummhorn, in old organs sometimes corno di bassetto) on the choir, and often an orchestral oboe (real imitation of the instrument). These are reed-stops. The dulciana and another soft stop, the salicional, saleional, or salicet (of similar strength, but slightly more pungent quality), are often placed on the choir. They are, however, hardly strong enough to be of much use there, and in the swell they are useful for effects of extreme softness. In very large instruments a fifteenth and a mixture are sometimes placed on the choir, which in this case has a complete series of diapason work. If the fifteenth and the mixtures are light enough the result is a sort of imitation of the tone of the old English organ. It also forms a useful echo to the great organ, *i.e.*, a passage played on the great may be repeated on the similar but fainter tone of the choir with the effect of an echo. In instruments of the largest size the choir is sometimes provided with a very small bourdon of 16-foot tone, which helps to give to the tone the character of that of a small full organ without reeds.

Solo organ.

The solo organ is comparatively modern, at all events in its present usual form. A fourth manual was not unknown in old German organs; but the contents of all four resembled each other in a general sort of way, and there was nothing like the English swell or the modern solo. The solo appears to have arisen with Cavaillé-Coll in France, and Hill in England, as a vehicle for the powerful reed-stops on heavy wind introduced by these builders. Thus the French term for the solo is "clavier des bombardes"; and in the earlier English solos the "tuba mirabilis" was usually prominent. A solo organ may suitably contain any of the following stops:—8 tromba (a powerful reed on heavy wind), 8 harmonic flute (powerful tone and heavy wind), 8 clarionet and 8 orchestral oboe (real imitations of the instruments), and 8 vox humana (conventional imitation of the human voice).

The vox humana is sometimes placed in the swell. The last three stops are reeds. They may be with advantage enclosed in a swell box, having a separate pedal. In very large instruments a complete series of both diapason and reed stops is occasionally placed on the solo. But there does not seem to be much advantage in this arrangement.

Pedal organ.

We now come to the pedal. This forms the general bass to the whole organ. Thirty-two foot stops only occur in the largest instruments; they are as follows:—32 open diapason (wood or metal), 32-foot tone bourdon, and 32 contra trombone, posaune, bombarde, sackbut (reed). The 32-foot open diapason, whether wood or metal, is usually made of large scale, and produces true musical notes throughout. Its musical effect in the lower part of its range is, however, questionable, so far as this depends on the possibility of recognizing the pitch of the notes. It adds great richness to the general effect, particularly in large spaces. The 32-foot tone bourdon is not usually a successful stop. It rarely produces its true note in the lower part of its range. The 32-foot reed on the pedal has long been a characteristic of the largest instruments. With the old type of reed it was rarely pleasant to hear. The manufacture has been greatly improved lately, and these large reeds are now made to produce a fairly smooth effect. Deep reed notes, when rich and good, undoubtedly form one of the principal elements in giving the impression of power produced by large organs. From this point of view they are of great importance. Nevertheless the effect of large pedal reeds is generally more satisfactory to the performer than to the listener.

The 16-foot pitch may be regarded as the normal pitch of the pedal; the principal stops are as follows:—16 open diapason (wood or metal), 16-foot tone bourdon, 16 violone (imitation of double bass), and 16 trombone or posaune (reed). The 16-foot open diapason on the pedal assumes different forms according to circumstances. As a rule the character is sufficiently indicated by the stop being of wood or metal. The wooden open is generally of very large scale, and produces a ponderous tone of great power and fulness, which is only suitable for the accompaniment of the full organ, or of very powerful manual combinations. Such a stop is, as a rule, unsuitable in organs of moderate size, unless supplemented by lighter 16s for ordinary purposes. The metal open is of considerably smaller scale (in fact all metal pipes are effectively of much smaller scale than wooden pipes of similar diameter). The metal gives a clear tone, lighter than that of large wooden pipes, and pleasanter for ordinary purposes. The metal open combines advantageously with a bourdon. In the largest organs both wood and metal open 16s may be suitably provided. Where metal pipes are made a feature in the organ-case, both the double open diapason in the great organ and the metal 16 of the pedal may be properly made of good metal (polished tin or spotted metal), and worked in to the design of the organ-case.[1] The same applies to the 32-foot metal opens of the largest instruments. This saves space in the interior, and gives the large pipes room to speak, which is apt to be wanting when they are placed inside. The 16-foot tone bourdon on the pedal may be made of any scale according to circumstances. If it is the chief bass of the organ it is made very large and with great volume of tone. Such stops are unsuitable for soft purposes, and a soft 16, usually a violone, is required in addition. If the loud department of the 16 tone is otherwise provided for the bourdon may be made of moderate strength. It may also be made very soft, like a manual bourdon. These three different strengths ought always to be provided for in an instrument of a complete character. The violone is also made of all three strengths. In a few cases it furnishes the principal bass; frequently it furnishes the moderate element; and it is often applied to obtain a very soft 16-foot tone. The 16-foot reed is very common. The observations made as to the effect of 32-foot reeds are applicable also in this case.

The 8-foot department of the pedal is only less important than the 16, because it is possible to replace it to a certain extent by coupling or attaching the manuals to the pedals. The usual 8-foot pedal-stops are as follows:—8 principal bass (metal or wood), 8 bass flute (stopped), 8 violoncello (imitation of the instrument), and 8 trumpet. The remarks made above as to the scale of open 16s apply with little change to the pedal principal. Only, since the manuals are generally coupled, it is perhaps best to provide the large scale wood-stop, which presents the powerful class of tone in which the manual diapasons are deficient. The bass flute is almost a necessity in combination with the light 16-foot tone. A composition ought to be provided by which the pedal can be reduced to these two elements by a single movement. The violoncello is sometimes used instead of the bass flute for the last-named purpose, for which, however, it is not so suitable. It is a favourite stop for some solo purposes, but is not of much general utility. The 8-foot trumpet serves to give clearness and point to the tone of the 16-foot reed.

In the short preface to Mendelssohn's *Organ Sonatas* it is stated that everywhere, even in pianissimo, it is intended that the 16-foot tone of the pedal should be accompanied

[1] Anything down to one-third tin and two-thirds lead is called tin. But "pure tin" should have over 90 per cent. of tin. Absolutely pure tin could not be worked. Spotted metal is said to have from one-third to two-thirds tin. Under one-third tin no spots are said to rise, and the mixture has the general characters of lead.

by 8-foot tone. For the purpose of realizing this as a general direction the soft 16-foot and 8-foot stops are required; large instruments are, however, occasionally found which possess nothing of the kind.

The following stops of higher pitch are occasionally found on the pedal:—$5\frac{1}{3}$ twelfth bass, 4 fifteenth bass, mixture, and 4 clarion. These serve to make the pedal tone practically independent of coupling to the manual, which is a matter of great importance, especially in the performance of certain compositions of Bach and other writers, who appear to have been independent of couplers.

The 8-foot and 4-foot reeds on the pedal afford the best, indeed almost the only means of performing some types of composition best known in the works of Bach, in which the pedal sounds a chorale in the 8-foot or 4-foot pitch, whilst an elaborate accompaniment is executed on the manuals. Where these pedal reeds are not present it is necessary to couple to the pedal an 8-foot or a 4-foot manual reed. The corresponding manual ceases to be available for the manual part of the composition; and, as this generally involves two manuals, one of which must possess a 16-foot stop, the performance is sometimes impracticable, even on large organs.

Second pedal.

In some foreign instruments two sets of pedals are provided, which may be described as great and choir pedals. The great pedal is in the usual position; the choir pedal is in front of the other, and sloping. It is so placed that the feet rest on it naturally when stretched out in front of the performer. There is a choir pedal of this kind in the organ in the minster at Ulm, built by Walcker of Ludwigsburg. It is a very large instrument, having 100 sounding stops. It has no compositions, which indeed are but little known in Germany; and without some arrangement such as this a soft pedal would hardly be obtainable. There are a few other instruments which have choir pedals, but they have not been introduced into England.

Arrangement of manuals.

In organs which have a single manual the characteristics of the great and choir organs are usually united. In organs which have two manuals the lower usually represents the united great and choir, the upper is the swell. In organs which have three manuals the lower is usually the choir, but sometimes combines choir and solo, the middle is the great, and the top is the swell. In organs which have four manuals the order is—solo, swell, great, choir, the solo being at the top and the choir at the bottom.

Compositions.

Compositions are mechanical contrivances for moving the stop-handles in groups at a time. The ordinary form consists of pedals, which project from the front just above the pedal keys. The arrangements are various. We may refer to the arrangement in the organ at Windsor, given later on. A species of composition was introduced by Willis some years ago, and has been adopted in many large English instruments, which acts by means of a series of brass disks placed just under the front of the keys of each manual, within reach of the thumb. These act by means of pneumatic levers. A slight pressure on one of the disks sets the machine attached to it in action, and the required change in the stops is made without any exertion on the part of the performer.

General mechanism.

The connexion between the keys and their pallets is made by various mechanisms, some of which are very ancient. In *square and trackerwork* (fig. 7) the old squares were made of wood. They resemble in function the squares used for taking bell-wires round a corner. The trackers are slight strips of wood, having screwed wires whipped on to their ends, which hold by leather buttons. The trackers play the part of the bell-wires. Where pressure has to be transmitted instead of a pull, thin but broad slips of wood are used, having pins stuck into their ends to keep them in their places. These are *stickers* (fig. 8). *Backfalls* (fig. 9) are narrow wooden levers turning on pins which pass through their centres. The *fan frame* (fig. 10) is a set of backfalls having one set of ends close together, usually corresponding to the keys; the other ends are spread widely apart. The *roller board* (fig. 11) is a more general mode of shifting the movements sideways. The roller is a slip of wood, or a bit of metal tube, which turns on two pins inserted into its ends. It has two arms projecting at right angles to its length. One of these receives the pull at one point, the other gives it off at another. In case a pull has to be transmitted to more than one quarter, a roller will sometimes have more than two arms. The name of *couplers* (fig. 12) is given to the mechanical stop by which the keys of one manual are made to take down those of another, or those of the pedal to take down those of the manuals. Some old forms of the mechanism could not be put on while any of the keys were depressed; others had a tendency to throw the fingers off the keys. These forms have been entirely superseded. That now used consists of a series of backfalls centred on a movable support. The one set of ends is connected with the moving keys; the other set of ends is pierced by the wires of the trackers or stickers from the keys to be moved. In the one position of the support these ends play freely over the wires; in the other they are brought up against the buttons of the trackers or against the stickers to be moved. The usual couplers are—each of the manuals to the pedal, swell to great, swell to great octave, swell to great sub-octave, swell to choir, choir to great sub-octave, and solo to great. The swell octave and sub-octave couplers are sometimes placed on the swell itself. The objection to this is, that, if they are used when the swell is coupled to the great organ, as is very commonly the case, the octaves are reached through two couplers. And, as couplers are not generally screwed up quite tight, the octaves are often not sufficiently put down to sound in tune. The choir to great sub-octave coupler was used chiefly as a substitute for a double on the great organ. It is common in organs of the transition period, but is not a good arrangement.

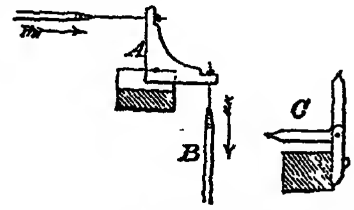

Fig. 7.—A, square; B, tracker; C, metal square.

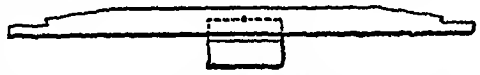

Fig. 9.—Backfall.

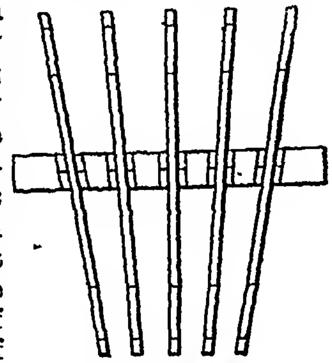

Fig. 10.—Fan frame.

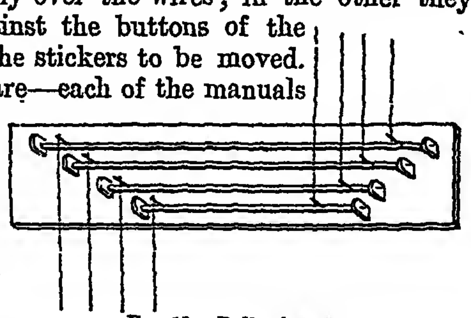

Fig. 11.—Roller board.

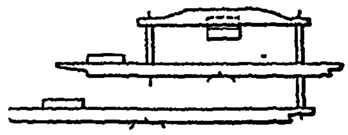

Fig. 12.—Coupler.

The *pneumatic lever* (fig. 13) consists of a small power bellows attached to each key, so that the depression of the key admits high-pressure wind to the power bellows. The power bellows then performs the work of opening the valves, &c. In large organs the work to be done would be beyond the reach of the most powerful finger without this device. Similar devices are sometimes applied to the compositions and other mechanical arrangements.

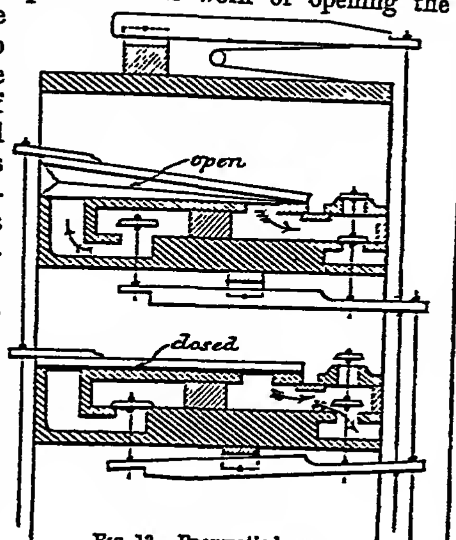

FIG. 13.—Pneumatic lever.

Pneumatic transmission, with many other mechanical devices, was invented by Willis. It consists of a divided pneumatic action. The pneumatic wind, instead of being at once admitted to the power bellows, is made to traverse a length of tubing, at the farther end of which it reaches the work to be done. This principle admits of application to divided organs, the pneumatic transmission passing under the floor, as in the organ at St Paul's Cathedral. It is peculiarly suitable for the pedals of large organs.

Ventils are valves which control the wind-supply of the different groups of stops. They were much recommended at one time as a substitute for compositions. The practical difference is that compositions shift the stop-handles, so that one can always see what there is on the organ; ventils leave the stop handles unmoved, so that the player is liable to be deceived. Other inconveniences might be mentioned, but it is enough to say that practical opinion appears decidedly to condemn the use of ventils.

The original *pedal boards* of Germany were flat and of very large scale. The early practice in England was to make them very small, as well as of short compass. Of late the compass C—*f′*, thirty notes, has been universally adopted with scales varying from $2\frac{1}{4}$ to $2\frac{1}{2}$ inches from centre to centre of the naturals; $2\frac{3}{8}$ inches is the scale now recommended. A large number of organs have been provided with what are called concave radiating pedal boards. These are most objectionable. All the best players dislike them. The objections are mainly two. They present different scales at different distances from the front; and, except just in front, they become so narrow that the smallest foot can hardly put down the pedals singly. This is fatal to legitimate playing, the essence of which consists in putting the feet over each other freely, so as to use the alternate method as much as possible; and this requires that the back of the pedal board shall be as available as the front. The concave parallel form appears to satisfy all requirements.

The diversities of the arrangements of different organs present a great difficulty. The best players take a certain time to master the arrangements of a strange instrument. With a view to the introduction of uniformity, a conference on the subject was arranged by the College of Organists in London, and a series of resolutions and a series of recommendations were published which deserve attention (1881). They go into considerable detail, and we must refer to the document itself. But we may mention that the parallel concave form is recommended for the pedal board, and $2\frac{3}{8}$ inches for the scale. The positions of the stops of the various organs are to be as follows.

Left.	Right.
Swell.	Solo.
Pedal.	Great.
Couplers.	Choir.

The order of compositions, &c., from piano to forte is to be in all cases from left to right. The groups of compositions are to be in the order from left to right—pedal, swell, couplers, great. Some think that too much has been here sacrificed to uniformity. It is thought that, as the swell and great as a rule are provided with compositions, their stops are more properly placed on the right, leaving the solo and choir on the left, as the left hand is the more easily spared. Also some prefer to have the compositions arranged with the pianos in the middle and the fortes at the ends, so that the risk of putting down a loud composition in mistake for a soft one is avoided.

Two other points of detail may be alluded to. One is the position of the pedal board with reference to the keys. The height from the middle of the pedals to the great organ keys, it is agreed, should be 32 inches. But as to the forward position there is a difference. The resolutions say that "a plumb-line dropped from the front of the great organ sharp keys falls 2 inches nearer the player than the front of the centre short key of the pedal board." The old arrangement gave usually $1\frac{1}{2}$ inches for this distance. But it is thought that the change has not gone far enough, and 4 inches has been found preferable. There is scarcely any single arrangement which is so important for the comfort of the player as having sufficient space in this direction (fig. 14). The second matter is the provision of some other means of acting on the swell than by the swell pedal. The use of the swell pedal is inconsistent with the proper use of both feet on the pedal keys; and there is no doubt that incorrect habits in this respect are commonly the result of the English use of the swell pedal. In fact, players sometimes keep one foot on the swell pedal all the time, so that proper pedal playing is impossible. Arrangements have been devised by means of which a movable back to the seat can be made the means of acting on the swell. The first "recommendation" of the College of Organists illustrates the requirement; it is, that "the consideration of organ-builders be directed to the widely-expressed desire for some means of operating on the swell in addition to the ordinary swell pedal."

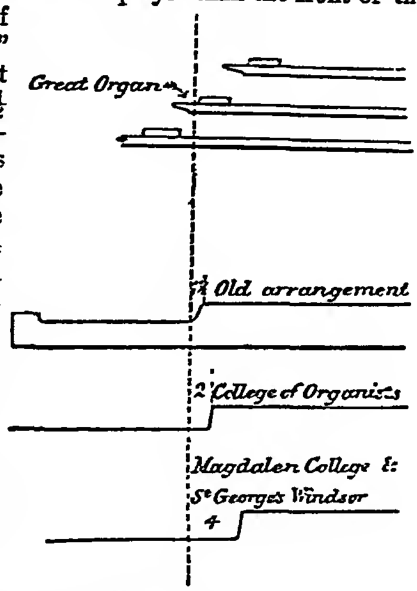

FIG. 14.—Relative position of manual and pedal

As an example of an organ of a complete but not enormously large character, we give the details of the organ at St George's chapel, Windsor, which has been recently rebuilt by Messrs. Gray and Davison, according to Mr. Walter Parratt's designs.

Four manuals, C to a‴, 58 notes.
Pedal, C to *f*, 30 notes.

Great Organ ($3\frac{1}{2}$-inch wind).

Double open diapason	16	Clarabella	8
Large open diapason	8	Principal	4
Open diapason	8	Harmonic flute	4
Stopped diapason	8	Twelfth	$2\frac{2}{3}$
		Fifteenth	2
		Sesquialtera[1]	III ranks
		Mixture[1]	II ranks
		Posaune	8
		Clarion	4

[1] These are the old mixtures.

Swell Organ (3-inch wind).

Lieblich bourdon	16
Open diapason	8
Stopped diapason	8
Dulciana	8
Vox cœlestis [1]	8
Principal	4
Octave dulcians	4
Fifteenth	2
Mixture [2]	III ranks
Contra fagotto	16
Cornopean	8
Oboe	8
Vox humana	8
Clarion	4

Choir Organ (2½-inch wind).

Dulciana	8
Keraulophon	8
Stopped diapason	8
Principal	4
Flute	4
Piccolo	2
Corno di bassetto (reed)	8

Solo Organ (5-inch wind).

Harmonic flute	8
Orchestral oboe	8
Tromba	8

Pedal Organ (4-inch wind).

Open diapason (wood)	16
Violone (metal)	16
Bourdon (wood)	16
Violoncello (metal)	8
Trombone (wood tubes)	16

Couplers.

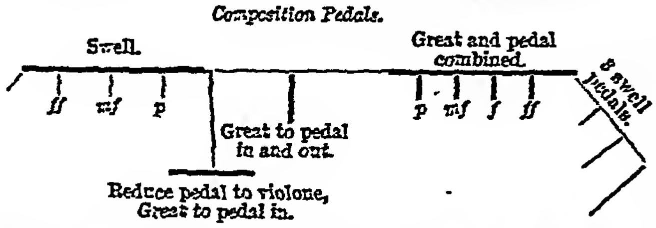
Solo to great.	Swell to pedal.
Swell to great.	Great to pedal.
Solo to pedal.	Choir to pedal.

Pneumatic action to great organ and its couplers.

The arrangement of the stops and compositions is as follows:—

Left.	*Over the keys.*	*Right.*
Solo.	Couplers.	Swell.
Choir.	Tremulant.	Great.
Pedal. (Knob below swell keys.)		

Composition Pedals.



The swell pedals control two sides of the swell box and the orchestral oboe. The vox humana is in a box which is always shut.

These swell pedals are on a new system, which admits of fixing them at any point, so that the tone can be determined to any strength.

History of the Organ.

The early history of the organ is very obscure.[3] As far back as classical times literary allusions occur occasionally to wind instruments involving the use of pipes and channels and reservoirs of air. Some form of bagpipe appears to have been alluded to in this way. Vitruvius has left a description of the hydraulicon, or hydraulic organ. It is clear that it must have been a machine of some complexity; but the way in which it acted is not intelligibly described.

Early allusions.

Athenæus also has an account of the water organ. There is a treatise on pneumatics by Hero of Alexandria, which contains apparently actual drawings of a pneumatic organ and of an hydraulic organ, with fairly clear descriptions. If these drawings are authentic they are remarkable; for the pipes shown present very much the appearance of modern organ-pipes, and they are arranged in a row with the longest in the middle, just as pipes are often arranged now. There is a bit of sculpture on the obelisk of Theodosius at Constantinople (latter part of 4th century) which represents an instrument having eight pipes standing in a row. The mouths are not shown, and the manipulation is apparently going on on the farther side, so that its nature is not shown. The wind is furnished by a sort of blacksmith's bellows, on which two men are standing, as if to give the pressure or "weight to the wind." It appears probable that organs were introduced into churches during the latter half of the first millennium A.D. As the keyboard does not appear to have been invented till after the close of this period, the notes can only have been sounded one at a time, and rapid successions cannot have been used. The notes seem to have been few in number, about ten, but each note had latterly a number of pipes.

Key-board.

A treatise on the construction of organs by a monk named Theophilus is assigned to the early part of the 11th century. While some of the practical work is recognizable, most of the descriptions are unintelligible. It appears clear, however, that no keyboard is mentioned.

The first keyboard is said to have been introduced into the organ in the cathedral at Magdeburg about the close of the 11th century. There were sixteen keys; and a drawing exists in a work of the 17th century[4] which purports to represent them. They are said to have been an ell long and 3 inches broad. The drawing represents a complete octave with naturals and short keys (semitones), arranged in the same relative positions as in the modern keyboard. As it is generally admitted that the semitones were not invented till later, it would seem that this drawing is probably not authentic. In early organs with keyboards the keys are said to have required blows of the fist to put them down. In these cases probably sounding the notes of the plain song was all that could be accomplished.

As to the precise time and conditions under which the keyboard assumed its present form we know nothing. It is commonly said that the change to narrow keys took place in the course of the 14th century, and that the semitones were introduced about the same time. But all these statements rest on the authority of writers long subsequent to the dates in question, and the actual facts appear to be unknown. Many examples of organ keyboards still exist, both in England and on the Continent, which have black naturals and white short keys (semitones). The organ in the church at Heiligenblut in the Tyrol had in 1870 two manuals, one having black naturals and white semitones, the other white naturals and black semitones. In this organ the stops were acted on by iron levers which moved right and left. It possessed a reservoir bellows of great capacity, and was altogether a remarkable instrument. Harpsichords with black keyboards also exist.

Bellows.

The mode of blowing practised about the time of the introduction of the first keyboard appears to have been that which ultimately developed into the method still generally used in Germany. There were a great many separate bellows, each like a magnified kitchen-bellows, but provided with a valve, so that the wind could not return into the bellows. One man had charge of two of these. Each foot was attached to one bellows, and the blower held on by a bar above. It was possible, by raising each of the two bellows in turn and then resting his weight upon it, to produce a constant supply of wind with the pressure due to his weight. A great many such bellows were provided, and it seems that each pair required one man; so that great numbers of blowers were employed. This description is again drawn from the 17th-century work before alluded to; and its very completeness and the clearness of the accompanying drawing seem suspicious. A slight modification is enough to change this method into the German one. Instead of fastening the feet to the bellows and pulling them up, the blower treads on a lever which raises the bellows. The bellows being loaded then supplies the wind of itself. The bellows thus used have diagonal hinges, and various expedients are employed to make them furnish steady wind. But the English system of horizontal reservoirs and feeders appears far superior.

While the notes were still few, and many pipes were connected with each note, the system of forming a chord on each note appears to have originated, which survives in the modern mixture. There was not at that time anything of the nature of stops; all the pipes connected with any one note sounded without exception whenever the note was made use of. The object probably was to give

[1] This stop consists of a soft stop slightly out of tune, producing a waving tone with the dulciana.

[2] These are the old mixtures.

[3] As regards this section the writer desires to acknowledge his obligations to Rimbault's *History of the Organ*, published with Hopkins's treatise.

[4] Prætorius, *Theatrum Instrumentorum*.

the single notes a powerful and dominating character, so as to enable them to lead the church song.

Pedal. The invention of the pedal may be set down to the 15th century. About that time the organ assumed on the Continent the general form which it has retained till lately, more especially in Germany. This may be described generally as having a compass of about four octaves in the manuals and of two octaves in the pedal, with occasionally extra notes at the top in both, and frequently "short octaves" at the bottom. German short octaves are as follows. The manual and pedal appear to terminate on E instead of C. Then the E key sounds C, F = F, F$\sharp$ = D, G = G, G$\sharp$ = E, and the rest as usual. There were often three, sometimes four, manuals in large organs. The character of all these was in general much the same, but they were more softly voiced in succession, the softest manual being sometimes spoken of as an echo organ. There are one or two examples of the echo as a fourth manual in England at the present time, in organs which have been designed more or less under German inspiration. The old echo was long ago superseded by the swell in England.

Cases. A few ancient cases survive in a more or less altered condition.[1] Of these the following are worthy of mention, as bearing on the question of date.

Sion (Switzerland). Gothic. A small instrument	1390
Amiens. Originally Gothic. Large, with 16-foot pipes	1429
Perpignan. Gothic. Large, with 32-foot pipes	1490
Lubeck. One of the finest Gothic organs in Europe. 32s	1504
(or, according to Hopkins, 1518).	

In all these the cases are sufficiently preserved to make it almost certain that pipes of the same lengths were originally employed. The actual pipes are generally modern. Shortly after this date we find Renaissance cases. At La Ferté Bernard (dep. Sarthe) part of the substructure is Gothic, and is known to be of date 1501; the organ above is Renaissance, and is known to be of date 1536. At St Maurice, Angers, an organ was built in 1511, with Renaissance case, two towers of *32-foot pipes*, *48 stops*, and a separate pedal. An account of the instrument in a procès verbal of 1533 furnishes good evidence. In the 16th century, therefore, the organ had attained great completeness, and the independent pedal was general on the Continent.

German organ. We cannot follow the history of German organs through the intervening centuries; but we propose to give the items of one of the principal organs of the Silbermanns, the great builders of the 18th century,—namely, that standing in the Royal Catholic Church, Dresden. Without being an enormously large instrument it is complete in its way, and gives a very good idea of the German organ. The account is taken from Hopkins. The date is 1754.

Great.

Manuals—C *to d''* in alt.	Pedal—C_1 to tenor *c*.

English organs. The chief difference between English organs and those of the Continent was that until the present century the pedal was absolutely unknown in England. The heavy bass given by the pedal being absent, a lighter style of voicing was adopted, and the manuals were usually continued down below the 8-foot C so as to obtain additional bass by playing octaves with the hands. Thus the old organ (date 1697) of Father Smith in St Paul's Cathedral had manuals descending to the 16-foot C (C_1), with two open diapasons throughout. Green's old organ at St George's, Windsor, had manuals descending to the 12-foot F, also two open diapasons throughout, no F$\sharp$. But the more usual practice was to make the manual descend to the $10\frac{2}{3}$ G, leaving out the G$\sharp$. At the Revolution most of the organs in England had been destroyed. Shortly afterwards Bernard Smith, a German, commonly called Father Smith, and Thomas and René Harris, Frenchmen, were largely employed in building organs, which were wanted everywhere. Father Smith perhaps had the greatest reputation of any builder of the old time, and his work has lasted wonderfully. There is a list in Rimbault of forty-five organs built for churches by him. The list of René Harris is scarcely less extensive.

The most important step in the development of the old English organ was the invention of the swell. This was first introduced into an organ built by two Jordans, father and son, for St Magnus's church near London Bridge, in 1712.

Burney writes (1771):—

> "It is very extraordinary that the swell, which has been introduced into the English organ more than fifty years, and which is so capable of expression and of pleasing effects that it may be well said to be the greatest and most important improvement that was ever made in any keyed instrument, should be utterly unknown in Italy; and, now I am on this subject, I must observe that most of the organs I have met with on the Continent seem to be *inferior* to ours by *Father Smith, Byfield, or Snetzler, in everything but size!* As the churches there are very often immense, so are the organs; the tone is indeed somewhat softened and refined by space and distance; but, when heard near, it is intolerably coarse and noisy; and, though *the number of stops in these large instruments* is very great, they afford but little variety, being for the most part duplicates in unisons and octaves to each other, such as the great and small 12ths, flutes, and 15ths; hence in our organs, not only the touch and tone, but the imitative stops, are greatly *superior to those of any other organs I have met with.*"

(As to these opinions, compare section on great organ open diapasons above, p. 830.)

In the course of the 18th century most of the old echoes were altered into swells, and the swell came into almost universal use in England. The development of the swell is inseparably associated with the peculiar quality of English swell reeds. These must have originated during the development of the swell. We hear of a "good reed voicer" named Hancock, who worked with Crang, changing echoes into swells. However it originated, the English reed is beautiful when properly made. It has recently entirely superseded the free reed, which had been long used in Germany. The original swells were usually short in compass downwards, frequently extending only to fiddle *g*. It is only lately that the value of the bass of the swell has been properly appreciated. Short-compass swells may be said to have now disappeared.

[1] In the remarks next following the writer is indebted for information to Hill's work on organ-cases.

Avery's old English organ.

The organ in St Stephen's, Coleman Street, is probably nearly in its original condition. It was built by Avery in 1775. At all events the following arrangements might very well have been the original ones. The pedal clavier without pipes is no doubt a subsequent addition, and is omitted.

Compass.

Great and choir—G_1 to e''', no $G_1\sharp$. Swell—fiddle *g* to e'''.

This gives an excellent idea of the old English organ. There are several different accounts of the introduction of pedals into England. It took place certainly before the end of the 18th century, but only in a few instances. And, for long after, the usual arrangement was simply to provide a pedal clavier, usually from F_1 or G_1 to *tenor c* or *d*, which took down the notes of the great organ. Unison diapason pipes (12-foot) were occasionally used. In one or two cases, as in the transition states of the old organ at St George's, Windsor, a 24-foot open diapason was employed as well as the unison stop. But a more usual arrangement, of a most objectionable character, was to combine the G_1—*c* pedal-board with a single octave of so-called pedal-pipes, extending from the 16-foot to the 8-foot C; so that, instead of a uniform progression in ascending the scale, there was always a break or repetition in passing C.

Pedals in England.

About the middle of the present century it began to be generally admitted that the German arrangement of the pedal was the better, and the practice gradually became general of providing a complete pedal-board of $2\frac{1}{2}$ octaves (*C*—*f'*), with at least one stop of 16-foot tone throughout, even on the smallest organs that pretended to be of any real use. The study of the classical works of Bach and Mendelssohn went hand in hand with this change; for that study was impossible without the change, and yet the desire for the study was one of the principal motives for it. In the meantime Bishop, an English builder, had invented composition pedals, which so greatly facilitate dealing with groups of stops. About the same time (1850) the mechanics of the organ were advanced by the general introduction of the pneumatic lever into large instruments; the whole mechanism of the organ was revolutionized by Willis's improvements; and the organ-builders of England, having obtained from the Continent the fundamental ideas necessary for completeness, advanced to a point at which they appear to be decidedly ahead. The English organ is now probably superior to that of any other country.

General Remarks on Organ Treatment.

Elementary difficulties.

The organ probably presents more difficulties than any other instrument in the way of a sound elementary mastery. A person of ordinary capacity may work at it for years before being able to play passages of moderate difficulty with confidence and correctness. The special difficulty appears to be chiefly mental, and arises from the number of things that have to be thought of simultaneously. It does not lie in the execution—at least not chiefly; for to play a hymn-tune correctly, the bass being taken with the pedals, the tenor with the left hand, and the two upper parts with the right, is a matter in which there is no execution required; but it is of great difficulty to an inexperienced player. Other distributions of parts—such as bass with pedals, treble with right hand on a solo stop (*e.g.*, clarionet), two inner parts with a soft open diapason, or something of the kind—are of much greater difficulty in the first instance. Another distribution is bass with pedals, melody with reed or solo combination in the tenor with left hand (an octave below its true pitch), inner parts with right hand on a soft open diapason, or something that balances. This is of far greater difficulty. All this can be practised with common hymn-tunes; but the performer who can do these things with ease is in some respects an advanced player.

Balance of tone.

What has been said above has much bearing on the arrangement of the different departments of the organ. It is one of the first requisites that as many balances of tone as possible should be available between the different manuals and the pedal. How many large organs there are on which such a balance can hardly be obtained!

Trios.

It would be difficult to lay too much stress on the above observations with respect to balance between the manuals. This is all-important in the performance of organ trios, such as the organ sonatas of Bach. In these compositions there are generally three notes sounding, which may be regarded as belonging to three different voices, of nearly equal strength, but different mean pitch, and, if possible, different quality; of these one is appropriated by each hand and one by the pedal. They are written in three lines, and are intended to be played on two manuals and the pedal. If there is a good choir organ, not too weak in tone, the clearest way is to play these things with a medium strength open diapason on the great organ for the right hand, the full 8-foot choir with or without the 4-foot flute with the left, and a metal 16-foot and 8-foot bass flute on the pedal. A usual course in England is to play the treble on a swell reed (oboe) with open swell, tenor on great diapason, and pedal as before; or treble great diapason, tenor oboe, pedal as before. Here there is some risk of the reed in the tenor being unpleasant. We may also suggest harmonic flute solo treble, open diapason great tenor, pedal as before. These compositions, however, admit of infinite variety in treatment. It appears probable that they were written for harpsichords, and in any case the intentions of the composer have not come down to us. As a matter of fact they are rarely successful on large English organs, on account of the want of balance between the manuals. And nothing could point the direction in which improvement is needed more than this observation.

Bach's organ fugues.

The fugues of Bach are the classical organ music *par excellence*. As to these it is also true that nothing has come down to us as to the composer's intentions, except that he generally played the fugues on the full organ with doubles. It does not seem clear that this was the case with the preludes; and, any way, the modern organ, with its facilities for managing the stops, appears to countenance a different treatment. The effect of doubles when a subject or tune is given out in solo is very bad. They may be drawn with advantage when the parts are moving in massive chords. The usual practice is perhaps to employ various manual effects of a light character until the pedal enters, and then to produce full organ in its various modifications, but always to aim at variety of tone. If a prelude begins with heavy chords and pedal, then produce full organ at once. If it then passes to lighter matter, reduce to some extent. Some begin a fugue on the stopped diapason of the great organ, add more as the parts enter, and continue working up throughout. But perhaps it is the better practice to throw in loud organ during the pedal parts, and soften between times.

Dignity and clearness.

One of the greatest requisites in organ-playing is dignity of treatment. This is continually competing with clearness. The chief mode of keeping the different parts distinct, where that is necessary, is by using reeds of a pronounced character. These reeds almost invariably verge on the comic, and anything more than the most sparing and careful employment of them is undesirable. Expression is not possible unless the stops are enclosed in a swell box,—a most desirable arrangement. In all cases hurry is to be avoided. A calm steadiness, a minute finish of all the phrasing, forms most of the difference between first and second rate players.

Modern music.

With reference to the general treatment of modern music we quote the preface to Mendelssohn's *Organ Sonatas*:—"In these sonatas very much depends on the correct choice of the stops; but, since every organ with which I am acquainted requires in this respect special treatment, the stops of given names not producing the same effect in different instruments, I have only indicated certain limits, without specifying the names of the stops. By *fortissimo* I mean the full organ; by *pianissimo*, usually one soft 8-foot stop alone; by *forte*, full organ without some of the most powerful stops; by *piano*, several soft 8-foot stops together; and so on. In the pedal I wish everywhere, even in pianissimo, 8-foot and 16-foot (tone) together, except where the contrary is expressly indicated, as in the sixth sonata [this refers to a passage where an 8-foot pedal is used without 16]. It is therefore left to the player to combine the stops suitably for the different pieces, but particularly to see that, in the simultaneous use of two manuals, the one keyboard is distinguished from the other by its quality, without forming a glaring contrast."

The treatment thus indicated is very different from that to which the suitability of English swell reeds for solo purposes has given rise. The effects commonly obtained by means of these reeds could hardly be more expressly described than in the final warning sentence above quoted. However, these reed effects possess great clearness, and, with the improved character of modern reeds and the toning down of the swell box, they are probably not so objectionable as what Mendelssohn had in his mind. Indeed the deficiency of good balances between flue stops answering the requirements above described is usually such that there is hardly any option but to employ swell reeds in such cases.

Consider particularly the pianissimo balances necessary for carrying out the above directions. In the first place it is clear that the soft 8-foot stops alluded to are not stops of extreme softness, such as the dulciana or salicional, as the attempt to produce a melody on such stops would everywhere be a failure. We must recognize for such purposes a further degree of softness, which may be denoted by *ppp*. We may take the average great organ stopped diapason as the measure of loudness of the soft stops *pp*; then it is requisite that on the choir or elsewhere there should be stops that will, especially in the tenor, combine and balance singly with the great stopped diapason in two-manual work. Choir stops would have to be decidedly stronger than usual for this purpose. Such a stop might be a small open diapason, or perhaps a gamba or keraulophon. Other balances of various kinds might be suggested. Some such must be present if the smooth and liquid character, which the soft parts of Mendelssohn's works at least were undoubtedly intended to possess, is to be preserved at all.

As a *ppp* is needed for extreme softness, so an *fff* is needed to express the exceptional degree of force attainable in modern instruments by adding the solo reed (tromba) to the ordinary full organ.

Modern music generally indicates in detail the treatment intended by the author. We may mention one matter which has come forward lately; this is the use of one hand on two manuals. This has become possible in consequence of the modern arrangement by which the manuals overhang.

For further details as to the history and construction of the organ, with numerous specifications, we must refer to the work of Hopkins and Rimbault on the organ. (R. H. M. B.)

ORGIES is a name given to certain rites in the worship of Dionysus-Bacchus. The rites, which were restricted to women, were celebrated in the winter among the hills in spots remote from city life. The women met in such places clad in fawn-skins (νεβρίς), with hair dishevelled, swinging the thyrsus and beating the cymbal; they danced and worked themselves up to a state of mad excitement. The holiest rites took place at night by the light of torches. A bull, the representative of the god, was torn in pieces by them as Dionysus-Zagreus had been torn; his bellowing reproduced the cries of the suffering god. The women tore the bull with their teeth, and the eating of the raw flesh was a necessary part of the ritual. Then the dead god was sought for. Some further rites, which varied in different districts, represented the resurrection of the god in the spring. On Mount Parnassus the women carried back Dionysus-Liknites, the child in the cradle. The most famous festival of the kind was the τριετηρίς, celebrated every second winter on Parnassus by the women of Attica and Phocis. The celebrants were called Mænads or Bacchæ. The ecstatic enthusiasm of the Thracian women, Κλώδωνες or Μιμαλλόνες, was especially distinguished. There is no doubt that in earlier times the murdered god was represented by a man, and the myths of Pentheus and Orpheus refer to the original form of the ritual.

ORIBASIUS. See MEDICINE, vol. xv. p. 804.

ORIGEN (*c.* 185-*c.* 254). Of all the theologians of the ancient church, with the possible exception of Augustine, Origen is the most distinguished and the most influential. He is the father of the church's science; he is the founder of a theology which was brought to perfection in the 4th and 5th centuries, and which still retained the stamp of his genius when in the 6th century it disowned its author. It was Origen who created the dogmatic of the church and laid the foundations of the scientific criticism of the Old and New Testaments. He could not have been what he was unless two generations before him had laboured at the problem of finding an intellectual expression and a philosophic basis for Christianity (Justin, Tatian, Athenagoras, Pantænus, Clement). But their attempts, in comparison with his, are like a schoolboy's essays beside the finished work of a master. Like all great epoch-making personalities, he was favoured by the circumstances of his life, notwithstanding the relentless persecution to which he was exposed. He lived in a time when the Christian communities enjoyed almost uninterrupted peace and held an acknowledged position in the world. By proclaiming the reconciliation of science with the Christian faith, of the highest culture with the gospel, Origen did more than any other man to win the Old World to the Christian religion. But he entered into no diplomatic compromises; it was his deepest and most solemn conviction that the sacred oracles of Christendom embraced all the ideals of antiquity. His character was as transparent as his life was blameless; there are few church fathers whose biography leaves so pure an impression on the reader. The atmosphere around him was a dangerous one for a philosopher and theologian to breathe, but he kept his spiritual health unimpaired, and even his sense of truth suffered less injury than was the case with most of his contemporaries. To us, indeed, his conception of the universe, like that of Philo, seems a strange medley, and one may be at a loss to conceive how he could bring together such heterogeneous elements; but there is no reason to doubt that the harmony of all the essential parts of his system was obvious enough to himself. It is true that in addressing the Christian people he used different language from that which he employed to the cultured; but there was no dissimulation in that,—on the contrary, it was a requirement of his system. Orthodox theology has never, in any of the confessions, ventured beyond the circle which the mind of Origen first measured out. It has suspected and amended its author, it has expunged his heresies; but whether it has put anything better or more tenable in their place may be gravely questioned.

Origen was born, perhaps at Alexandria, of Christian parents in the year 185 or 186. As a boy he showed evidence of remarkable talents, and his father Leonidas gave him an excellent education. At a very early age, about the year 200, he listened to the lectures of Pantænus and Clement in the catechetical school. This school, of which the origin is unknown, was the first and for a long time the only institution where Christians were instructed simultaneously in the Greek sciences and the doctrines of the Holy Scriptures. Alexandria had been, since the days of the Ptolemies, a centre for the interchange of ideas between East and West—between Egypt, Syria, Greece, and Italy; and, as it had furnished Judaism with an Hellenic philosophy, so it also brought about the alliance of Christianity with Greek philosophy. Asia Minor and the West developed the strict ecclesiastical forms by means of which the church closed her lines against heathenism, and especially against heresy; in Alexandria Christian ideas were handled in a free and speculative fashion and worked out with the help of Greek philosophy. Till near the end of the 2d century the line between heresy and orthodoxy was less rigidly drawn there than at Ephesus, Lyons, Rome, or Carthage. In the year 202 a persecution arose, in which the father of Origen became a martyr, and the family lost their livelihood. Origen, who had distinguished himself by his intrepid zeal, was supported for a time by a lady of rank, but began about the same time to earn his bread by teaching; and in 203 he was placed, with the sanction of the bishop Demetrius, at the head of the catechetical school. Even then his attainments in the whole circle of the sciences were extraordinary. But the spirit of investigation impelled him to devote himself to the highest studies, philosophy and the exegesis of the Sacred Scriptures. With indomitable perseverance he applied

himself to these subjects; although himself a teacher, he regularly attended the lectures of Ammonius Saccas, and made a thorough study of the books of Plato and Numenius, of the Stoics and the Pythagoreans. At the same time he endeavoured to acquire a knowledge of Hebrew, in order to be able to read the Old Testament in the original. His manner of life was ascetic; the sayings of the Sermon on the Mount and the practical maxims of the Stoics were his guiding stars. Four oboli a day, earned by copying manuscripts, sufficed for his bodily sustenance. A rash resolve led him to mutilate himself that he might escape from the lusts of the flesh, and work unhindered in the instruction of the female sex. This step he afterwards regretted. As the attendance at his classes continually increased—pagans thronging to him as well as Christians —he handed over the beginners to his friend Heraclas, and took charge of the more advanced pupils himself. Meanwhile the literary activity of Origen was increasing year by year. He commenced his great work on the textual criticism of the Scriptures; and at the instigation of his friend Ambrosius, who provided him with the necessary amanuenses, he published his commentaries on the Old Testament and his dogmatic investigations. In this manner he laboured at Alexandria for twenty-eight years (till 231-232). This period, however, was broken by many journeys, undertaken partly for scientific and partly for ecclesiastical objects. We know that he was in Rome in the time of Zephyrinus, again in Arabia, where a Roman official wanted to hear his lectures, and in Antioch, in response to a most flattering invitation from Julia Mammæa (mother of Alexander Severus, afterwards emperor), who wished to become acquainted with his philosophy. In the year 216—the time when the imperial executioners were ravaging Alexandria—we find Origen in Palestine. There the bishops of Jerusalem and Cæsarea received him in the most friendly manner, and got him to deliver public lectures in the churches. In the East, especially in Asia Minor, it was still no unusual thing for laymen, with permission of the bishop, to address the people in the church. In Alexandria, however, this custom had been given up, and Demetrius took occasion to express his disapproval and recall Origen to Alexandria. Probably the bishop was jealous of the high reputation of the teacher; and a coolness arose between them which led, fifteen years later, to an open rupture. On his way to Greece (apparently in the year 230) Origen was ordained a presbyter in Palestine by his friends the bishops. This was undoubtedly an infringement of the rights of the Alexandrian bishop; at the same time it was simply a piece of spite on the part of the latter that had kept Origen so long without any ecclesiastical consecration. Demetrius convened a synod, at which it was resolved to banish Origen from Alexandria. Even this did not satisfy his displeasure. A second synod, composed entirely of bishops, determined that Origen must be deposed from the presbyterial status. This decision was communicated to the foreign churches, and seems to have been justified by referring to the self-mutilation of Origen and adducing objectionable doctrines which he was said to have promulgated. The details of the incident are, however, unfortunately very obscure. No formal excommunication of Origen appears to have been decreed; it was considered sufficient to have him degraded to the position of a layman. The sentence was approved by most of the churches, in particular by that of Rome. At a later period Origen sought to vindicate his teaching in a letter to the Roman bishop Fabian, but, it would seem, without success. Even Heraclas, his former friend and sharer of his views, took part against him; and by this means he procured his own election shortly afterwards as successor to Demetrius.

In these circumstances Origen thought it best voluntarily to retire from Alexandria (231-232). He betook himself to Palestine, where his condemnation had not been acknowledged by the churches any more than it had been in Phœnicia, Arabia, and Achaia. He settled in Cæsarea, and very shortly he had a flourishing school there, whose reputation rivalled that of Alexandria. His literary work, too, was prosecuted with unabated vigour. Enthusiastic pupils sat at his feet (see the *Panegyric* of Gregory Thaumaturgus), and the methodical instruction which he imparted in all branches of knowledge was famous all over the East. Here again his activity as a teacher was interrupted by frequent journeys. Thus he was for two years together at Cæsarea in Cappadocia, where he was overtaken by the Maximinian persecution; here he worked at his recension of the Bible. We find him again in Nicomedia, in Athens, and twice in Arabia. He was called there to combat the unitarian christology of Beryllus, bishop of Bostra, and to clear up certain eschatological questions. As he had formerly had dealings with the house of Alexander Severus, so now he entered into a correspondence with the emperor Philip the Arabian and his wife Severa. But through all situations of his life he preserved his equanimity, his keen interest in science, and his indefatigable zeal for the instruction of others. In the year 250 the Decian persecution broke out, Origen was arrested, imprisoned, and maltreated. But he survived these troubles—it is a malicious invention that he recanted during the persecution—and lived a few years longer in active intercourse with his friends. He died, probably in the year 254 (consequently under Valerian), at Tyre, where his grave was still shown in the Middle Ages.

Writings.—Origen is probably the most prolific author of the ancient church. "Which of us," asks Jerome, "can read all that he has written?" The number of his works was estimated at 6000, but that is certainly an exaggeration. Owing to the increasing unpopularity of Origen in the church, a comparatively small portion of these works have come down to us in the original. We have more in the Latin translation of Rufinus; but this translation is by no means trustworthy, since Rufinus, assuming that Origen's writings had been tampered with by the heretics, considered himself at liberty to omit or amend heterodox statements. Origen's real opinion, however, may frequently be gathered from the *Philocalia*—a sort of anthology from his works prepared by Basil the Great and Gregory Nazianzenus. The fragments in Photius and in the *Apology of Pamphilus* serve for comparison. The writings of Origen consist of letters, and of works in textual criticism, exegesis, apologetics, dogmatic and practical theology.

(1) Eusebius collected more than a hundred of Origen's letters, arranged them in books, and deposited them in the library at Cæsarea (*H. E.*, vi. 36). In the church library at Jerusalem (founded by the bishop Alexander) there were also numerous letters of this father (Euseb., *H. E.*, vi. 20). But unfortunately they have all been lost except two,—one to Julius Africanus (about the history of Susanna) and one to Gregory Thaumaturgus. There are, besides, a couple of fragments.

(2) Origen's textual studies on the Old Testament were undertaken partly in order to improve the manuscript tradition, and partly for apologetic reasons, to clear up the relation between the LXX. and the original Hebrew text. The results of more than twenty years' labour were set forth in his *Hexapla* and *Tetrapla*, in which he placed the Hebrew text side by side with the various Greek versions, examined their mutual relations in detail, and tried to find the basis for a more reliable text of the LXX. The *Hexapla* was probably never fully written out, but excerpts were made from it by various scholars at Cæsarea in the 4th century; and thus large sections of it have been

saved.[1] Origen worked also at the text of the New Testament, although he produced no recension of his own.

(3) The exegetical labours of Origen extend over the whole of the Old and New Testaments. They are divided into *Scholia* (σημειώσεις, short annotations, mostly grammatical), *Homilies* (edifying expositions grounded on exegesis), and *Commentaries* (τόμοι). In the Greek original only a very small portion has been preserved; in Latin translations, however, a good deal. The most important parts are the homilies on Jeremiah, the books of Moses, Joshua, and Luke, and the commentaries on Matthew, John, and Romans. With grammatical precision, antiquarian learning, and critical discernment Origen combines the allegorical method of interpretation—the logical corollary of his conception of the inspiration of the Scriptures. He distinguishes a threefold sense of scripture, a grammatico-historical, a moral, and a pneumatic,—the last being the proper and highest sense. He thus set up a formal theory of allegorical exegesis, which is not quite extinct in the churches even yet, but in his own system was of fundamental importance. On this method the sacred writings are regarded as an inexhaustible mine of philosophical and dogmatic wisdom; in reality the exegete reads his own ideas into any passage he chooses. The commentaries are of course intolerably diffuse and tedious, a great deal of them is now quite unreadable; yet, on the other hand, one has not unfrequently occasion to admire the sound linguistic perception and the critical talent of the author.[2]

(4) The principal apologetic work of Origen is his book κατὰ Κέλσου (eight books), written at Cæsarea in the time of Philip the Arabian. It has been completely preserved in the original. This work is invaluable as a source for the history and situation of the church in the 2d century; for it contains nearly the whole of the famous work of Celsus (Λόγος ἀληθής) against Christianity. What makes Origen's answer so instructive is that it shows how close an affinity existed between Celsus and himself in their fundamental philosophical and theological presuppositions. The real state of the case is certainly unsuspected by Origen himself; but many of his opponent's arguments he is unable to meet except by a speculative reconstruction of the church doctrine in question. Origen's apologetic is most effective when he appeals to the spirit and power of Christianity as an evidence of its truth. In details his argument is not free from sophistical subterfuges and superficial reasoning.[3]

(5) Of the dogmatic writings we possess only one in its integrity, and that only in the translation of Rufinus,[4] Περὶ ἀρχῶν (On the Fundamental Doctrines). This work, which was composed before 228, is the first attempt at a dogmatic at once scientific and accommodated to the needs of the church. The material is drawn from Scripture, but in such a way that the propositions of the *regula fidei* are respected. This material is then formed into a system by all the resources of the intellect and of speculation. Origen thus solved, after his own fashion, a problem which his predecessor Clement had not even ventured to grapple with. The first three books treat of God, the world, the fall of spirits, anthropology, and ethics. "Each of these three books really embraces, although not in a strictly comprehensive way, the whole scheme of the Christian view of the world, from different points of view, and with different contents." The fourth book explains the divinity of the Scriptures, and deduces rules for their interpretation. It ought properly to stand as first book at the beginning. The ten books of *Stromata* (in which Origen compared the teaching of the Christians with that of the philosophers, and corroborated all the Christian dogmas from Plato, Aristotle, Numenius, and Cornutus) have all perished, with the exception of small fragments; so have the tractates on the resurrection and on freewill.[5]

(6) Of practical theological works we have still the Προτρεπτικὸς εἰς μαρτύριον and the Σύνταγμα περὶ εὐχῆς. For a knowledge of Origen's Christian estimate of life and his relation to the faith of the church these two treatises are of great importance. The first was written during the persecution of Maximinus Thrax, and was dedicated to his friends Ambrosius and Protoctetus. The other also dates from the Cæsarean period; it mentions many interesting details, and concludes with a fine exposition of the Lord's Prayer.

(7) In his own lifetime Origen had to complain of falsifications of his works and forgeries under his name. Many pieces still in existence are wrongly ascribed to him; yet it is doubtful whether a single one of them was composed on purpose to deceive. The most noteworthy are the *Dialogues* of a certain Adamantius "de recta in Deum fide," which seem to have been erroneously attributed to Origen so early as the 4th century.

Outline of Origen's View of the Universe and of Life.—The system of Origen was formulated in opposition to the Greek philosophers on the one hand, and the Christian Gnostics on the other.[6] But the science of faith, as expounded by him, bears unmistakably the stamp both of Neo-Platonism and of Gnosticism. As a theologian, in fact, Origen is not merely an orthodox traditionalist and believing exegete but a speculative philosopher of Neo-Platonic tendencies. He is, moreover, a judicious critic. The union of these four elements gives character to his theology, and in a certain degree to all subsequent theology. It is this combination which has determined the peculiar and varying relations in which theology and the faith of the church have stood to each other since the time of Origen. That relation depends on the predominance of one or other of the four factors embraced in his theology.

As an orthodox traditionalist Origen holds that Christianity is a practical and religious saving principle, that it has unfolded itself in an historical series of revealing facts, that the church has accurately embodied the substance of her faith in the *regula fidei*, and that simple faith is sufficient for the renewal and salvation of man. As a philosophical idealist, however, he transmutes the whole contents of the faith of the church into ideas which bear the mark of Neo-Platonism, and were accordingly recognized by the later Neo-Platonists as Hellenic.[7] In Origen, however, the mystic and ecstatic element is held in abeyance. The ethico-religious ideal is the sorrowless condition, the state of superiority to all evils, the state of order and of rest. In this condition man enters into likeness to God and blessedness; and it is reached through contemplative isolation and self-knowledge, which is divine wisdom. "The soul is trained as it were to behold itself in a mirror, it shows the divine spirit, if it should be found worthy of such fellowship, as in a mirror, and thus discovers the traces of a secret path to participation in the divine nature." As a means to the realization of this ideal,

Lit. Zeitung*, 1878 No. 22, 1879 No. 9; *Orig. c. Cels.*, ed. Selwyn, 1876.

[4] There are, however, extensive fragments of the original in existence.

[5] See Redepenning, *Origenis de principiis*, first sep. ed., Leips., 1836; Schnitzer, *Orig. über die Grundlehren des Glaubens*, an attempt at reconstruction, 1835.

[6] The opposition to the unitarians within the church must also be kept in mind.

[7] Porphyry says of Origen, κατὰ τὰς περὶ πραγμάτων καὶ τοῦ θείου δόξας Ἑλληνίζων (Euseb., *H.E.*, vi. 19).

Origen introduces the whole ethics of Stoicism. But the link that connects him with churchly realism, as well as with the Neo-Platonic mysticism, is the conviction that complete and certain knowledge rests wholly on divine revelation, *i.e.*, on oracles. Consequently his theology is cosmological speculation and ethical reflexion based on the Sacred Scriptures. The Scriptures, however, are treated by Origen on the basis of a matured theory of inspiration in such a way that all their facts appear as the vehicles of ideas, and have their highest value only in this aspect. That is to say, his gnosis neutralizes all that is empirical and historical, if not always as to its actuality, at least absolutely in respect of its value. The most convincing proof of this is that Origen (1) takes the idea of the immutability of God as the regulating idea of his system, and (2) deprives the historical "Word made flesh" of all significance for the true Gnostic. To him Christ appears simply as the Logos who is with the Father from eternity, and works from all eternity, to whom alone the instructed Christian directs his thoughts, requiring nothing more than a perfect—*i.e.*, divine—teacher. In such propositions historical Christianity is stripped off as a mere husk. The objects of religious knowledge are beyond the plane of history, or rather—in a thoroughly Gnostic and Neo-Platonic spirit—they are regarded as belonging to a supramundane history. On this view contact with the faith of the church could only be maintained by distinguishing an exoteric and an esoteric form of Christianity. This distinction was already current in the catechetical school of Alexandria, but Origen gave it its boldest expression, and justified it on the ground of the incapacity of the Christian masses to grasp the deeper sense of Scripture, or unravel the difficulties of exegesis. On the other hand, in dealing with the problem of bringing his heterodox system into conformity with the *regula fidei* he evinced a high degree of technical skill. An external conformity was possible inasmuch as speculation, proceeding from the higher to the lower, could keep by the stages of the *regula fidei*, which had been developed into a history of salvation. The system itself aims in principle at being thoroughly monistic; but, since matter, although created by God out of nothing, was regarded merely as the sphere in which souls are punished and purified, the system is pervaded by a strongly dualistic element. The immutability of God requires the eternity of the Logos and of the world. At this point Origen succeeded in avoiding the heretical Gnostic idea of God by assigning to the Godhead the attributes of goodness and righteousness. The pre-existence of souls is another inference from the immutability of God, although Origen also deduced it from the nature of the soul, which as a spiritual potency must be eternal. Indeed this is the fundamental idea of Origen—"the original and indestructible unity of God and all spiritual essences." From this follows the necessity for the created spirit, after apostacy, error, and sin, to return always to its origin in God. The actual sinfulness of all men Origen was able to explain by the theological hypothesis of pre-existence and the premundane fall of each individual soul. He holds that freedom is the inalienable prerogative of the finite spirit; and this is the second point that distinguishes his theology from the heretical Gnosticism. The system unfolds itself like a drama, of which the successive stages are as follows:—the transcendental fall, the creation of the material world, inaugurating the history of punishment and redemption, the clothing of fallen souls in flesh, the dominion of sin, evil, and the demons on earth, the appearing of the Logos, His union with a pure human soul, His esoteric preaching of salvation, and His death in the flesh, then the imparting of the Spirit, and the ultimate restoration of all things. The doctrine of the restoration appeared necessary because the spirit, in spite of its inherent freedom, cannot lose its true nature, and because the final purposes of God cannot be foiled. The end, however, is only relative, for spirits are continually falling, and God remains through eternity the creator of the world. Moreover, the end is not conceived as a transfiguration of the world, but as a liberation of the spirit from its unnatural union with the sensual. Here the Gnostic and philosophical character of the system is particularly manifest. The old Christian eschatology is set aside; no one has dealt such deadly blows to Chiliasm and Christian apocalypticism as Origen. It need hardly be said that he spiritualized the church doctrine of the resurrection of the flesh. But, while in all these doctrines he appears in the character of a Platonic philosopher, traces of rational criticism are not wanting. Where his fundamental conception admits of it, he tries to solve historical problems by historical methods. Even in the christology, where he is treating of the historical Christ, he entertains critical considerations; hence it is not altogether without reason that in after times he was suspected of "Ebionitic" views of the Person of Christ. Not unfrequently he represents the unity of the Father and the Son as a unity of agreement and harmony and "identity of will."

Although the theology of Origen exerted a considerable influence as a whole in the two following centuries, it certainly lost nothing by the circumstance that several important propositions were capable of being torn from their original setting and placed in new connexions. It is in fact one of the peculiarities of this theology, which professed to be at once churchly and philosophical, that most of its formulæ could be interpreted and appreciated *in utramque partem*. By arbitrary divisions and rearrangements the doctrinal statements of this "science of faith" could be made to serve the most diverse dogmatic tendencies. This is seen especially in the doctrine of the Logos. On the basis of his idea of God Origen was obliged to insist in the strongest manner on the personality, the eternity (eternal generation), and the essential divinity of the Logos.[1] On the other hand, when he turned to consider the origin of the Logos he did not hesitate to speak of Him as a *κτίσμα*, and to include Him amongst the rest of God's spiritual creatures. A *κτίσμα*, which is at the same time ὁμοούσιον τῷ Θεῷ, was no contradiction to him, simply because he held the immutability, the pure knowledge, and the blessedness which constituted the divine nature to be communicable attributes. In later times both the orthodox and the Arians appealed to his teaching, both with a certain plausibility; but the inference of Arius, that an imparted divinity must be divinity in the second degree, Origen did not draw. With respect to other doctrines also, such as those of the Holy Spirit and the incarnation of Christ, &c., Origen prepared the way for the later dogmas. The technical terms round which such bitter controversies raged in the 4th and 5th centuries are often found in Origen lying peacefully side by side. But this is just where his epoch-making importance lies, that all the later parties in the church learned from him. And this is true not only of the dogmatic parties; solitary monks and ambitious priests, hard-headed critical exegetes,[2] allegorists, mystics, all found something congenial in his writings. The only man who tried to shake off the theological influence of Origen was Marcellus of Ancyra, who did not succeed in producing any lasting effect on theology.

The attacks on Origen, which had begun in his lifetime,

[1] "Communis substantiæ est filio cum patre; *ἀπόρροια* enim ὁμοούσιος videtur, *i.e.*, unius substantiæ cum illo corpore ex quo est ἀπόρροια."

[2] *E.g.*, Dionysius of Alexandria; compare his judicious verdict on the Apocalypse.

did not cease for centuries, and only subsided during the time of the fierce Arian controversy. It was not so much the relation between pistis and gnosis—faith and knowledge—as defined by Origen that gave offence, but rather isolated propositions, such as his doctrines of the pre-existence of souls, of the soul and body of Christ, of the resurrection of the flesh, of the final restoration, and of the plurality of worlds. Even in the 3d century Origen's view of the Trinity and of the Person of Christ was called in question, and that from various points of view. It was not till the 5th century, however, that objections of this kind became frequent. In the 4th century Pamphilus, Eusebius of Cæsarea, Athanasius, the Cappadocians, Didymus, and Rufinus were on the side of Origen against the attacks of Methodius and many others. But, when the zeal of Epiphanius was kindled against him, when Jerome, alarmed about his own reputation, and in defiance of his past attitude, turned against his once honoured teacher, and Theophilus, patriarch of Alexandria, found it prudent, for political reasons, and out of consideration for the uneducated monks, to condemn Origen,—then his authority received a shock from which it never recovered. There were, doubtless, in the 5th century church historians and theologians who still spoke of him with reverence, but such men became fewer and fewer. In the West Vincent of Lerins held up Origen as a warning example (*Commonit.*, 23), showing how even the most learned and most eminent of church teachers might become a misleading light. In the East the exegetical school of Antioch had an aversion to Origen; the Alexandrians had utterly repudiated him. Nevertheless his writings were much read, especially in Palestine. The monophysite monks appealed to his authority, but could not prevent Justinian and the fifth œcumenical council at Constantinople (553) from anathematizing the teaching of Origen. It is true that many scholars (*e.g.*, Hefele, *Conciliengesch.*, ii. p. 858 *sq.*) deny that Origen was condemned by this council; but Möller rightly holds that the condemnation is proved (*Realencyklop. f. protest. Theol. u. Kirche*, vol. xi. p. 113).

Sources and Literature.—Next to the works of Origen (see Redepenning, "Des Hieronymus wiederaufgefundenes Verzeichniss der Schriften des Origens," in *Zeit. f. d. hist. Theol.*, 1851, p 66 *sq.*) the most important sources are:—Gregory Thaumat., *Panegyricus in Orig.*; Eusebius, *H. E.*, vi.; Epiphanius, *Hær.*, 64; the works of Methodius, the Cappadocians, Jerome (see *De vir. ill.*, 54, 61), and Rufinus; Vincent. Lerin., *Commonit.*, 23; Palladius, *Hist. Laus.*, 147; Justinian, *Ep. ad Mennam* (Mansi, ix. p. 487 *sq.*); Photius, *Biblioth.*, 118, &c. There is no complete critical edition of Origen's works. The best edition is that of Car. and C. Vinc. Delarue, 4 vols. fol., Paris, 1733-59,—reprinted by Lommatzsch, 25 vols. 8vo, Berlin, 1831-48, and by Migne, *Patrol. curs. compl.*, ser. Gr., vols. xi.-xvii. Several new pieces have been edited by Gallandi and A. Mai. Amongst the older works on Origen those of Huetius (printed in Delarue, vol. iv.) are the best; but Tillemont, Fabricius, Walch (*Historie d. Ketzereien*, vii. pp. 362-760), and Schröckh also deserve to be mentioned. In recent times the doctrine of Origen has been expounded in the great works on church history by Baur, Dorner, Bohringer, Neander, Möller (*Geschichte der Kosmologie in der griechischen Kirche*), and Kahnis (*Die Lehre vom h. Geist*, vol. i.); compare with these the works on the history of philosophy by Ritter, Erdmann, Ueberweg, and Zeller. Of monographs, the best and most complete is Redepenning, *Origenes, eine Darstellung seines Lebens und seiner Lehre*, 2 vols., 1841, 1846. Compare Thomasius, *Orig.*, 1837; Kruger, "Ueber das Verhältniss des Orig. zu Ammonius Sakkas," in the *Ztschr. f. hist. Theol.*, 1843, i. p. 46 *sq.*; Fischer, *Comment. de Orig. theologia et cosmologia*, 1846; Ramers, *Orig. Lehre von der Auferstehung des Fleisches*, 1851; Knittel, "Orig. Lehre von der Menschwerdung," in the *Theol. Quartalschr.*, 1872; Schultz, "Christologie des Orig.," in the *Jahrb f. protest. Theol.*, 1875; Mehlhorn, "Die Lehre von der menschlichen Freiheit nach Orig.," in *Zeitschr. f. Kirchengesch.*, vol. ii., 1878; Freppel, *Origène*, vol. i., 2d ed., Paris, 1875. (A. HA.)

ORIHUELA, a town and episcopal see of Spain, in the southern portion of the province of Alicante, 13 miles north-east from Murcia and about 15 from the sea, is situated in a beautiful and exceedingly fertile "huerta," at the foot of a limestone ridge of moderate height, and on both sides of the Segura, here crossed by two bridges. There are remains of an old fort on the hill commanding the town; and the gateway on the side of Valencia—the Puerta del Colegio—is a fine lofty arch, surmounted by an emblematic statue and the city arms. The most prominent buildings are the episcopal palace (1733), with a frontage of 600 feet, but partly ruinous; the town-house (1843), containing the municipal archives and a considerable number of curious and important documents of national history; and the cathedral, a comparatively small Gothic structure built on the site of a former mosque in the 14th century, and enlarged and tastelessly restored in 1829. There are large barracks on the outskirts, and many noblemen have town houses or "palaces" in Orihuela. There are also a considerable number of convents, now suppressed. The university of Orihuela, founded in 1568 by the archbishop of Valencia, was closed in 1835, part of the revenue being applied to the support of a college affiliated to the university of Valencia. Besides numerous primary schools there are a theological seminary and a normal school. The final separation of Orihuela from the diocese of Cartagena took place in 1564. The inhabitants are largely engaged in agriculture, the trade in fruit (oranges and citrons, pomegranates, dates), as well as in cereals, oil, and wine, being considerable. There is a lively and picturesque weekly market. The manufactures, which are of secondary importance, include textile fabrics, leather, saltpetre, and hats; dyeing is also carried on. The population of the ayuntamiento was 20,929 in 1877.

Orihuela is not mentioned in ancient geography, for a proposed identification with the Orcelis of Pliny is almost certainly wrong. As Auriela or Aurivalet, on the other hand, it figures frequently in the annals of the Moorish period; in 713 it was held successfully for some time by Theodemir against Abd-al-Aziz. It was conquered by Jayme of Aragon, for his father-in-law Alphonso of Castile, in 1265. It suffered sack during the disturbances at the beginning of the reign of Charles V. (1520), and again in the War of Succession (1705). Local annals specially mention the plague of 1648, the flood of 1651, and the earthquake of 1829.

ORINOCO, a river in the north of South America, which falls into the Atlantic on the north-east seaboard between 60° 20′ and 62° 30′ W. long., after draining an area of at least 366,000 square miles (belonging to Venezuela and Colombia) in a course of about 1500 miles. Between the source of its westmost affluent, the Guaviare, and that of its eastmost, the Caroni, there is a difference of 14 degrees of longitude. The head-waters of the main stream rise on the southern slope of the Sierre Parime; but the branch which keeps the name Orinoco has not yet been traced by any European, and the position of the lake from which, according to native report, it issues can only be vaguely fixed. Michelena y Rójas, who ascended the Orinoco as far as the mouth of the Mawaca (itself about 30 feet deep), found it even there a deep and navigable river; and a little way lower down it receives no inconsiderable accession from the Ocamo and Padamo. Below Esmeralda, a settlement in 65° 50′ W. long., long known as the limit of definite exploration, occurs one of the most remarkable bifurcations in the world; while the main stream holds on in a north-west direction, a branch called the Casiquiare turns south and, increased by numerous small tributaries, runs for about 180 miles to the Rio Negro (an affluent of the Amazons) with so rapid a current that, while a boat takes only four natural days to descend, the return voyage requires twenty to thirty days. In the neighbourhood of San Fernando de Atabapo (in 4° 2′ N. lat. and 68° 10′ W. long., a miserable village, but officially the capital of the Venezuelan province of the Amazons, and famous in the history of the river) the Orinoco is joined by the united waters of the Atabapo, the Ynirida, and the Guaviare,—the Guaviare receiving the Ynirida

about 10 or 15 miles west of San Fernando and then meeting the Atabapo opposite the village. The Guaviare is the first of the great rivers which bring down the waters of the Andes to the Orinoco, and is fit for steamboat traffic a long way up. From its junction with the Guaviare to the great rapid of Mariapiri (a distance of about 180 miles) the Ynirida, which was explored in 1872 by Frédéric Montolieu, hastens through a rugged country with a swift and frequently interrupted stream; above Mariapiri, and as far as Guácamayo (Montolieu's farthest), it forms, on the other hand, a succession of lakes and lagoons with hardly any current (*Bull. Soc. Géogr.*, Paris, 1880). Though smaller than either the Guaviare, the Ynirida, or the Orinoco, the Atabapo gives its northward direction to the united river, which below the confluence widens out into a noble flood several miles broad, but before long has its channel contracted and twisted and broken by the rough granitic rocks of the country through which it has to force its way. About 80 miles bring the river to the great cataracts of Maypures, and a few miles more to that of Atures; both are complete barriers to upward navigation, and, since Humboldt's glowing description, have been ranked among the most striking pieces of river scenery in South America (Humboldt and Bonpland, *Voy. au Nouv. Continent*, vol. ii. pp. 360-363). Some distance below Atures is the confluence of the Meta, a powerful many-watered affluent from the Andes, which has been ascended by steamer within 60 miles of Bogotá; but the Orinoco still continues northward till, meeting the Apure, which drains the whole Merida Cordillera, it turns westwards through the great Venezuelan valley. In its onward course it receives a great many tributaries from both north and south, the former being comparatively short, but the latter, especially the Caura and Caroni, rising in the highlands hundreds of miles away. About 50 miles below the mouth of the Caroni and 120 miles from the sea begins the enormous delta, embracing 200 miles of coast. The southmost branch, Boca de Navios or Boca de Varime, continues in the line of the river; the Manamo or Vagre branch strikes off almost at right angles northward to the Gulf of Paria or Golfo Triste. The annual inundation of the Orinoco, which makes a kind of false start in April, and, gradually increasing in May, June, and July, reaches its height in September, is extensive enough to lay the country under water in some places for scores of miles inland. As most of the regions through which it passes are in a state of nature, and there is hardly, with the exception of ANGOSTURA (*q.v.*), a town of any considerable size on the banks of either main stream or affluents, this noble river-system is but little turned to account for commerce. Not only, however, is it easily navigable for steamers for nearly 800 miles, but, as the lower part of its course lies in the line of the trade-winds, sailing craft are able to make their way slowly upwards against the current. Even at the junction of the Guaviare the height above the sea is only 744 feet.

In 1498 Columbus entered Golfo Triste, and probably observed the northern mouths of the Orinoco, and in 1499 the main channel appears to have been noted by Ojeda. The first to attempt the ascent of the river was Diego de Ordaz in 1535, who reached the mouth of the Meta. For its scientific exploration we are mainly indebted to José Iturriaga and José Solano (1756), Humboldt (1800), and Michelena y Rójas (1855-1856).

See Gumilla, *El Orinoco ilustrado* (Madrid, 1741); Michelena y Rójas, *Exploracion oficial* (Brussels, 1867).

ORIOLE, from the Old French *Oriol* and that from the Latin *aureolus*, the name once applied to the bird, from its golden colouring, which is now generally admitted to be the *Vireo* or ICTERUS (vol. xii. p. 696) of classical authors—the *Oriolus galbula* of Linnæus—but now commonly used in a much wider sense. The Golden Oriole, which is the type of the Family *Oriolidæ* of modern ornithologists, is a far from uncommon spring-visitor to the British Islands; but the conspicuous plumage of the male—bright yellow contrasted with black, chiefly on the wings and tail—always attracts attention, and generally brings about its death. Yet a few instances are known in which it is supposed to have bred in England. The nest is a beautifully interwoven fabric, suspended under the horizontal fork of a bough, to both branches of which it is firmly attached, and the eggs are of a shining white sometimes tinged with pink, and sparsely spotted with dark purple. On the Continent it is a well-known if not an abundant bird, and its range in summer extends so far to the east as Irkutsk, while in winter it is found in Natal and Damaraland. In India it is replaced by a closely allied form, *O. kundoo*, chiefly distinguishable by the male possessing a black streak behind as well as in front of the eye; and both in Asia and Africa are several other species more or less resembling *O. galbula*, but some depart considerably from that type, assuming a black head, or even a glowing crimson instead of the ordinary yellow colouring, while others again remain constant to the dingy type of plumage which characterizes the female of the more normal form. Among these last are the aberrant species of the group *Mimetes* or *Mimeta*, belonging to the Australian Region, respecting which Mr Wallace pointed out, first in the Zoological Society's *Proceedings* (1863, pp. 26-28), and afterwards in his *Malay Archipelago* (ii. pp. 150-153), the very curious facts—as yet only explicable on the theory of "mimicry"—of which mention has already been made (HONEY-EATER, vol. xii. p. 139). It is a singular circumstance that this group *Mimeta* first received its name from Captain King (*Survey &c. of Australia*, ii. p. 417) under the belief that the birds composing it belonged to the Family *Meliphagidæ*, which had assumed the appearance of Orioles, whereas Mr Wallace's investigations tend to show that the imitation (unconscious, of course) is on the part of the latter. The external similarity of the *Mimeta* and the *Tropidorhynchus* of the island of Bouru, one of the Moluccas, is perfectly wonderful, and has again and again deceived some of the best ornithologists, though the birds are structurally far apart. Another genus which has been referred to the *Oriolidæ*, and may here be mentioned, is *Sphecotheres*, peculiar to the Australian Region, and distinguishable from the more normal Orioles by a bare space round the eye. (A. N.)

ORION, the name of a constellation which has been the centre of many legends in Greece. It bears the form of a warrior carrying a club, and wearing a girdle which is composed of three very beautiful stars. Its disappearance in the autumn is the prelude to storms and rain. The legendary hero Orion, or, as Pindar calls him, Oarion, was according to Homer a giant, fairer and taller than the Aloides. Eos, the dawn-goddess, loved him, but the gods were angry; Artemis slew him in Ortygia with kindly shaft. A doubtful passage in the *Odyssey* calls him a mighty hunter. The later poets give various discrepant accounts of his parentage. They usually connect him with some deed of violence to a maid, either the daughter of Œnopion in Chios, or the nymph Upis in Delos, or even Artemis herself. Others say that Artemis loved him, and was induced, by an artifice of the angry Apollo, to shoot him unwittingly. The Old Testament name of the constellation appears to be *kĕsîl*, the fool or impious (Amos v. 5; Job ix. 9, xxxviii. 31). In Arabic and Semitic it is called the giant. Late writers (Cedrenus and the *Paschal Chronicle*) speak of a Persian identification of Orion with Nimrod.

ORISSA, a province of British India, forming a division or commissionership under the jurisdiction of the lieutenant-governor of Bengal, situated between 19° 28′ and 22° 34′ 15″ N. lat. and between 83° 36′ 30″ and 87° 31′ 30″ E. long. It forms the extreme south-western portion of Bengal,

bounded on the N. and N.E. by Chutiá Nágpur and Lower Bengal proper, E. and S.E. by the Bay of Bengal, S. by Madras, and W. by the Central Provinces.

Orissa consists of two distinct territories—a fertile alluvial delta, comprising the three British districts of Cuttack, Balasor, and Purí, occupying an area of 8056 square miles; and a wild region of sparsely populated tributary Hill States, with an area of 16,084 square miles, the latter walling out the former from the central Indian plateau. In the latter district the two small territories of Angul and Banki (area 997 square miles) are subject to British management. Including these, the area of British Orissa is 9053 square miles.

British Orissa.—The Orissa delta is formed from the deposits of the Mahánadí, the Bráhmaní, and the Baitaraní, which converge towards the coast, to within 30 miles of each other, upon Orissa. The three rivers, together with two minor streams, the Sálandí and Subanrekhá, represent an accumulated drainage of 63,350 square miles, which, during the height of the hot weather, amounts only to a discharge of 1690 cubic feet per second. The average cold-weather discharge is 5360 cubic feet, but during the rains it rises to 2,760,000 cubic feet. This enormous mass of water falls suddenly upon a narrow level strip of country in which the river-beds are altogether inadequate to carry it off. The Orissa canal-system now affords an outlet to much of this surplus water, which it also utilizes for irrigation.

The population of the British districts was 3,730,735 in 1881, distributed over an area of 9053 square miles. The Hindus form the great mass of the population (3,634,049 in 1881), Mohammedans numbering 85,611, and aboriginal tribes still following their primitive modes of worship 10,923. The population is entirely rural, the people living almost solely by husbandry. In 1881 there were only five towns in the province containing upwards of 5000 inhabitants:—Cuttack (42,656), the headquarters of the provincial administration, and the starting-point of the great system of canals which irrigate the province; Purí (22,095), the capital of the third district of Orissa, and the religious capital of the province; Balasor (20,265), the official headquarters of the district of the same name, and the site of the earliest British factory on the seaboard of Bengal; Kendrapára (15,969); and Jáipur (11,283), also a great religious centre, with numerous ruined Sivaite temples.

The whole of Orissa is holy ground. On the southern bank of the Baitaraní shrine rises after shrine in honour of Siva, the All-Destroyer. On leaving the stream the pilgrim enters Jáipur, literally the city of sacrifice, the headquarters of the region of pilgrimage sacred to the wife of the All-Destroyer. There is not a fiscal division in Orissa without its community of cenobites, scarcely a village without consecrated lands, and not a single ancient family that has not devoted its best acres to the gods. Every town is filled with temples, and every hamlet has its shrine. The national reverence of the Hindus for holy places has been for ages concentrated on Purí, sacred to Vishnu under his title of Jagannáth, the Lord of the World.

Rice forms the great staple, every variety of it being grown, from the dwarf plant, 18 inches high, on the dry uplands, to the long-stemmed paddy which rears its head above 6 or 7 feet of water. Other crops consist of wheat, many varieties of pulse, oil-seeds, hemp, tobacco, cotton, sugar-cane, betel-leaf, tubers, and vegetables of many kinds. Besides its copious water-supply in time of high flood, the province has a local rainfall of 62½ inches per annum. Nevertheless, the uncontrolled state of the water-supply has subjected the country from time immemorial to droughts no less than to inundation. Thus the terrible famine of 1865-66, which swept away one-fourth of the entire population, was followed in 1866 by a flood which destroyed crops to the value of £3,000,000. Since then much has been done by Government to husband the abundant water-supply.

The early history of the kingdom of Orissa (*Odra-desa*), as recorded in the archives of the temple of Jagannáth, is largely mythical. A blank in the records from about 50 B.C. to 319 A.D. corresponds to a period of Yavana occupation and Buddhist influence, during which the numerous rock monasteries of Orissa were excavated. The founder of the Kesari or Lion dynasty, which ruled from 474 to 1132 A.D., is said to have restored the worship of Jagannáth, and under this line the great Sivaite temple at Bhuvaneswar was constructed. In 1132 a new line (the Gangetic dynasty) succeeded, and Vishnu took the place of Siva in the royal worship. This dynasty was extinguished in 1532-34, and in 1578, after half a century of war, Orissa became a province of the Mogul empire. In 1751 it passed to the Marhattás and suffered great miseries under their rule till the British conquest in 1803.

Orissa Tributary States.—These form a cluster of eighteen dependent territories or chiefships in the mountainous background of the Orissa division, occupying a succession of wooded mountain and rocky ranges, enclosing the rich valleys of the Mahánadi, Bráhmani, and Baitarani. The following table gives a list of the states, with their area in square miles and their population.

TRIBUTARY STATES OF ORISSA IN 1881.

	States.	Area.	Population.		States.	Area.	Population.
1	Athgarh......	168	31,079	10	Khandpara .	244	66,296
2	Athmallik....	730	21,774	11	Morbhanj	4,243	385,737
3	Barambá	134	29,772	12	Narsinhpur ..	199	32,593
4 } 5 }	Bod and *Khondmal*	2,064	130,103	13	Nilgiri	278	60,972
				14	Nayagarh .. .	588	114,622
6	Daspalla	568	41,605	15	Pal Lahára .	452	14,887
7	Dhenkanal ..	1,463	203,316	16	Banpur	293	36,530
8	Hindol	312	23,802	17	Tálcher	399	35,290
9	Keunjhar	3,096	215,612	18	Tigaria	46	19,850
					Total....	15,187	1,409,142

The largest *town* in the whole of the Tributary States is Khandpára, with 5543 inhabitants. It lies on the right bank of the Mahánadi, and is a considerable seat of trade.

Tillage is conducted in two methods, common to the whole Tributary States: (1) rice cultivation in hollows and on low lands which have a command of irrigation; (2) upland or *táila* cultivation, upon newly-cleared patches of land, which depends entirely on the local rainfall. In the valleys, where the mountain rivulets can be utilized, the peasants throw a dam across the stream and store up the water. The lower levels thus secure a supply of moisture the whole year round, and wet rice cultivation goes on throughout the twelve months. In the uplands the forests are cut down and burnt upon the spot; and the soil, thus enriched with salts, yields abundant crops of early rice, oil-seeds, and cotton. At the end of four or five years such clearings are abandoned for new ones, and the land relapses into jungle.

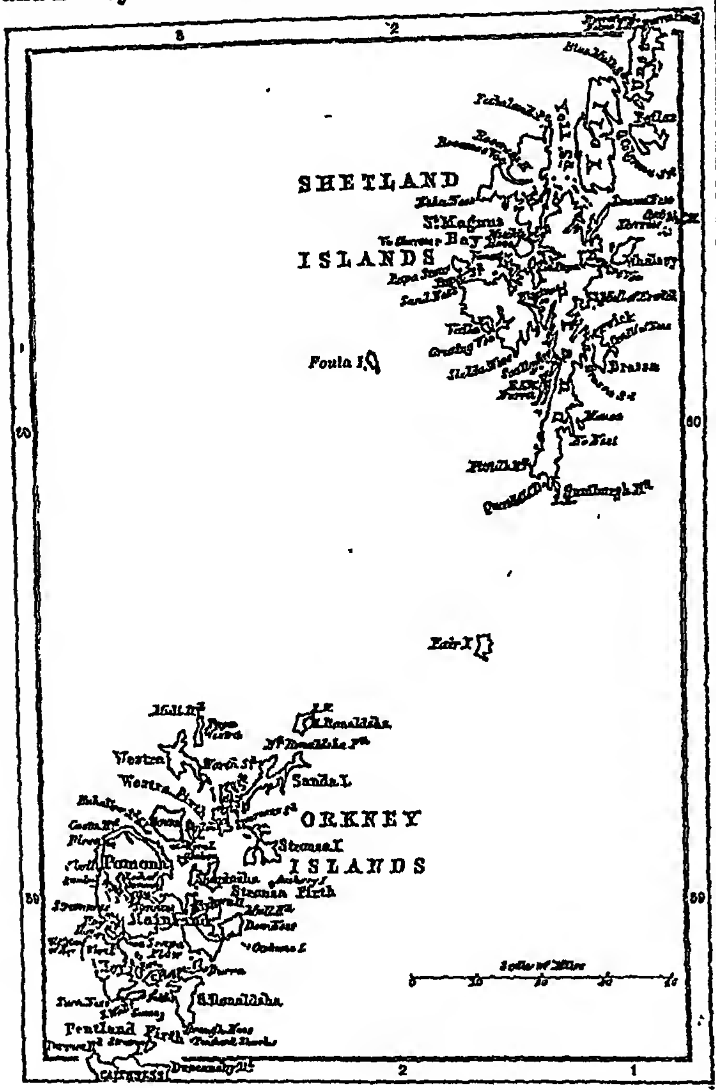
The states are under the political superintendence of the British commissioner of Orissa.

ORIZABA, or ORIZAVA, a city of Mexico, in the state of Vera Cruz, is situated at a height of 3975 feet above the sea in a well-wooded valley 65 miles south-west of Vera Cruz, on one of the two high roads between that city and Mexico, and since 1872 on the Vera Cruz and Mexico Railway. It is a thriving place of 16,000 inhabitants, has a good exchange, a theatre, and two hospitals, spins cotton, and manufactures cotton and woollen cloth, and trades in tobacco, sugar, rum, and other local products. Originally called Izhuatlan, Orizaba is one of the oldest cities of Mexico. At the time of the Spanish conquest it formed part of the Aztec kingdom. In 1521 the natives massacred a large number of Spaniards. In 1862 Orizaba was the headquarters of the French army, which inflicted a defeat on the Mexicans on the outskirts of the city. Six miles north of the city stands the Pico de Orizaba or Citlaltepetl, "The Mountain of the Star," an extinct volcano 17,665 feet high, and thus one of the loftiest summits in the continent. It was ascended by W. F. Reynolds of the United States Topographical Engineers in 1848.

ORKNEY AND SHETLAND, a county of Scotland, formed of two separate groups of islands in the North Sea. The Orkneys are situated between 58° 41′ and 59° 24′ N. lat. and between 2° 22′ and 3° 25′ W. long., and are separated from the mainland of Scotland by the Pentland Firth, the breadth of which between Brough Ness in South Ronaldshay and Duncansby Head, Caithness, is about 7 miles. The Shetlands lie to the north-east of the Orkneys, between 59° 50′ and 60° 52′ N. lat. and between 0° 55′ and 2° 14′ W. long. The distance from Dennis Head in Orkney to Sumburgh Head in Shetland is about 50 miles, but Fair Isle, which is included in Shetland, is situated midway between the two main groups. The total area of the Orkneys and Shetlands is 593,352 acres or about 927 square miles, the area of the Orkneys being 240,476 acres, and that of the Shetlands 352,876 acres.

In the Orkney group there are fifty-six islands and islets,

of which twenty-nine are inhabited, the others, which are called "holms," being frequently made use of for pasture. Besides Pomona or the Mainland, which has an area equal to all the others combined, the principal islands are, to the north, Rousay, Westray, Papa-Westray, North Ronaldshay, Sanday, Eday, Stronsay, and Shapinshay, and to the south, Hoy, North Walls, South Walls, Flotta, South Ronaldshay, and Burray. The members of the Shetland group are more



numerous than the Orkneys, consisting of about a hundred islands and islets; besides the Mainland, the more important are Yell, Unst, and Fetlar to the north, Whalsay and Bressay to the east, and East and West Burra, Papa-Stour, Muckle Roe, and Foula to the west. Except towards the west the surface of the Orkneys is comparatively flat, and in some cases, as in Sanday, the coast is so low as to be a frequent cause of shipwreck. The island of Hoy consists principally of lofty black barren rocks, of which the Ward Hill attains a height of 1564 feet. In the southern part of the Mainland, to the west of Kirkwall, the hills also reach a considerable elevation, the highest summits being Wideford Hill near Kirkwall (740 feet) and the Ward Hill of Orphir (880 feet); and there is another hilly region in the north-west of the Mainland, opposite the island of Rousay. The centre of Rousay is occupied by hills of considerable height. On the west of Hoy perpendicular precipices of great height descend sheer to the Atlantic. The outline of the islands is very irregular, and through the numerous firths and sounds the tides rush with great rapidity, forming occasionally whirlpools called *roosts*, which in stormy weather frequently suck in fishing-boats and prove dangerous even to large vessels.

The coast-scenery of the Shetland group is strikingly picturesque. The islands present an irregular rocky surface generally rising into hills of considerable elevation, the highest summit being Roeness Hill (1475 feet) in the Mainland. By the action of the waves the rocks have been worn into numerous fantastic shapes, and the coast-line is also deeply indented by bays and "voes" or sea-lochs, caused partly by denudation and partly by glacial action. The greater part of the coast is stern and precipitous, but Sumburgh Head, the Noup of Noss, Fitful Head, the island of Papa-Stour with its surrounding rocks, Foula (especially on its western side), the Drongs and adjoining rocks of the parish of Northmavine with the coast-line from Roeness Voe to Haevdadal Head, and Unst the most northern of the group may be singled out for their picturesque beauty or impressive grandeur. The action of the sea has formed numerous caves, the more remarkable of which are the immense Orkneyman's Cave near the Bard of Bressay, and the fantastic caves of Papa-Stour.

Geology.—The geological formation of the Orkneys is very similar to that of the adjoining mainland, and consists almost entirely of the lower Old Red Sandstone of the flagstone series. A red and yellow sandstone series occupies part of Sanday, Eday, Burray, Flotta, and South Ronaldshay, and a long narrow strip of the Mainland to the south of Kirkwall. The mountainous district of Hoy belongs to the upper Old Red Sandstone, in which are interbedded volcanic rocks consisting of amygdaloidal lavas and ashes, and forming the terraces of the northern slopes of the Hoy hills. These rocks rest unconformably on the lower Old Red Sandstone. North-west from Stromness Bay to Inga Ness there is an outcrop of crystalline rocks consisting of granite and micaceous gneiss. The flagstone series, especially in the neighbourhood of Stromness, contains numerous fossils,—ichthyolites, crustaceans, and plants being all represented. From the character of the striated surfaces of the rocks, and the presence of foreign rocks in the boulder-clay, it has been concluded that the Orkneys were subjected to a glacial action crossing from the North Sea to the Atlantic; and there are also traces of local glaciers, especially at Hoy.

The geological formation of the Shetlands, like that of the Orkneys, belongs principally to the lower Old Red Sandstone and the metamorphic rocks on which they rest unconformably; but the proportion between the two species of rocks is reversed, the metamorphic rocks cropping to the surface throughout the greater part of the Shetland group. The central portion of the islands, including the north-western half of the Mainland and its eastern seaboard in the parish of Northmavine, Whalsay, Yell, and the western seaboard of Unst, is occupied chiefly by micaceous and hornblendic gneiss with limestones and quartzites. In the southern portion of the Mainland the clay-slate series, with associated limestones and quartzites, prevails. In Unst and Fetlar there are large masses of serpentine and gabbro, and diorite occupies a large area in the districts of Delting and Northmavine. The lower Old Red Sandstone occupies the islands of Foula and Bressay, skirts the eastern seaboard of the Mainland from Lerwick southwards, and includes the greater part of Walls. It is associated with a series of igneous rocks, especially in the western district of Northmavine, and there is also an intrusive series. Even more striking evidence of glacial action exists in Shetland than in Orkney. The metamorphic rocks are very rich in beautiful minerals, especially along the coast of Northmavine, among the varieties being felsite, epidote, actinolite, serpentine, anthophyllite, fluor-spar, steatite, magnetite, and cyanite. Both in Orkney and Shetland there are large deposits of peat.

Climate and Agriculture.—The temperature, both of the Orkneys and of the Shetlands, presents smaller variations than that of Scotland or England. The yearly average is a little over 45° Fahr., the average for the coldest months—

January, February, and March—being nearly 39°, and for the warmest months—July, August, and September—about 53°. Though fogs are common, the rainfall is not excessive, but it is higher in Shetland than in Orkney. As the temperature is influenced by the Gulf Stream, the coldest month of the year is March, when the tide reaches its lowest point. The soil of Orkney varies in different islands, but generally it is either a sandy loam or a strong but friable clay, and remarkably fertile. Large quantities of seaweed, as well as lime and marl, are available for manure. Since the opening up of more constant communication with the south, and the construction of a complete system of roads, begun in 1857, the system of cultivation has undergone a complete transformation. Many of the holdings in Orkney are now occupied by farmers from Scotland.

Between 1875 and 1880 the number of holdings in Orkney increased from 3147 to 3319, and their area from 93,618 acres to 104,958. In 1880 2873 holdings, or more than two-thirds of the total number, did not exceed 50 acres each, while 279 ranged from 50 to 100 acres, 131 from 100 to 300, and 36 were above 300. The total number of acres under cultivation in 1883 was 112,148, of which 38,459 were under corn crops, 32,051 rotation grasses, 22,755 permanent pasture, and 1031 fallow. Of the corn crops, 32,781 acres were under oats and 5641 under barley or bere, while 14,387 of the green crops were under turnips and 3104 under potatoes. Horses, which are for the most part a small and active breed, numbered 6092 in 1883, of which 4884 were used solely for agricultural purposes. Cattle numbered 25,624, of which 9405 were cows and heifers in milk or in calf. Shorthorned and polled Angus are now the most common breeds, cattle-feeding being largely practised. Sheep, which in 1883 numbered 31,548, are now chiefly Cheviots and a cross between them and Leicesters, but the native sheep (identical with those of Shetland) are still kept in considerable numbers in Hoy and South Ronaldshay. Pigs numbered 4745.

In Shetland there has been no agricultural progress corresponding to that in operation in Orkney, the principal reason being insufficiency of soil, which in many cases has to be made or increased by collecting turf. Between 1875 and 1880 the number of holdings decreased from 3839 to 3604, but the area under cultivation increased from 52,256 to 53,357 acres. In 1880 3529 holdings did not exceed 50 acres each, while 36 ranged from 50 to 100 acres, 30 from 100 to 300, and 11 were above 300. Although there are some good arable farms in a few favoured districts, the majority are small crofts held on a yearly tenancy by the fishermen along with their cottages. For the most part the cottages are only slightly improved specimens of the original cabin, the fireplace of at least the "but" end being in the centre of the apartment, which was formerly shared with calves, pigs, and other young animals. The cows are now for the most part housed in separate buildings. Originally the rent was paid in kind, and it was a general custom for the landlord or tacksman to compel the crofter to barter a considerable portion of the fruits of his industry for provisions and clothing, but this mode of payment has now fallen into disuse. The cottages are generally grouped together in small hamlets called "touns." The size of a croft varies from 5 to 10 acres; but the old Norwegian measurement by merks is still retained. Originally the land was held on the "runrig" system—that is, different owners held alternate ridges—but now in most cases each holding is separate. The implement anciently used for turning over the soil was the Norwegian plough drawn by four oxen abreast, but as the holdings became subdivided and distinctly separated from each other it was superseded by the small sharp spade now in almost universal use. Until lately implements with wheels were scarcely known, and even yet the crofters generally carry out even the manure for the land in straw baskets slung over the shoulders. A system of roads, constructed during the potato famine of 1846-49, is now maintained under a County Road Act, passed in 1864, and wheeled vehicles are in general use. According to the agricultural returns of 1883 there were 58,393 acres under cultivation, of which 10,528 were under corn crops, 4511 green crops, and 41,628 permanent pasture. No system of rotation is practised. Of the corn crops 8050 acres were under oats and 2478 under bere; and of the green crops 3357 acres were under potatoes and 943 under turnips. Originally the grain supplies were obtained almost wholly from the Orkneys, and for a long period grey and black oats and bere or bigg were the only species grown, but now white oats are quite common. Frequently the grain does not ripen till the end of October or beginning of November. The culture of the cabbage is said to have been introduced by a detachment of Cromwell's soldiers, potatoes in 1730, and turnips in 1807. Black and red currants ripen in sheltered situations. Horses in 1883 numbered 5305, of which only 908 were used solely for agricultural purposes; cattle numbered 21,345, of which 8132 were cows and heifers in milk or in calf; sheep numbered 81,163, and pigs 3788. The small ponies peculiar to the islands are now becoming scarce, though entire ponies are greatly in demand for working underground in collieries. The native cattle are a diminutive breed with small horns and short legs. They are said to possess many of the points of the best breeds. The beef is remarkable for tenderness and flavour; and, when well fed, the cows yield a large supply of rich milk. In some districts crosses have been introduced. The native sheep of Shetland possess many of the characteristics of goats. The ewes, as well as the rams, have generally short horns, and the wool is long and of very fine quality. White, black, speckled grey, and a peculiar russet brown called "moorat" are the prevailing colours. It is the common custom to tear out the wool from the roots by the hand, as this is said to ensure a finer second crop. Black-faced and Cheviot sheep are kept in some places. Large numbers of geese and other kinds of poultry are kept.[1]

According to the *Valuation Roll*, 1883-84, Orkney was divided among 1149 proprietors, possessing 220,873 acres, with an annual value of about £82,416, or 7s 5d per acre. According to the *Parliamentary Return* of 1873 546 of the proprietors, or about 42 per cent. at that date, possessed less than 1 acre, and the following 10 possessed upwards of 5000 acres each:—J. G. M. Heddle, 50,410; earl of Zetland, 29,846; D. Balfour, 29,054; R. Baikie, 7846; R. J. Hebden, 7500; F. T. Burroughs, 6693; A. S. Graeme, 6444; trustees of late J. Stewart of Brugh, 6243; T. Traill, 5780; trustees of the late G. Traill, 5031. Shetland in 1883-84 was divided among 575 proprietors, possessing 352,876 acres, with a total value of £44,108, or nearly 2s 6d per acre. In 1873 240 of the proprietors, or about 45 per cent., possessed less than 1 acre, 15 possessed upwards of 5000 acres, 13 above 10,000, and the following 5 above 20,000 acres each:—trustees of Busta estate, 29,820; curators of W. A. Bruce, 25,180; Lady Nicolson, 24,785; T. M. Cameron, 24,363; A. J. Grierson, 22,006.

Fauna.—The faunas of the two groups of islands are very similar. Remains of deer have been found in the Orkneys, although few, if any, remained in the time of the Norse jarls. For some centuries hares were extinct, but they were reintroduced about 1830. Rabbits are very numerous in some districts. The otter and walrus are met with. Seals may occasionally be observed basking on the rocks, especially in the neighbourhood of the Vie Skerries off the western coast of the Mainland (Shetlands); and whales, both large and small, are frequently captured in the bays and sounds. The common porpoise is abundant, and the grampus also haunts the coasts. Nearly all the *Falconidæ* found anywhere else in Britain at one time frequented the Orkneys, and the hen-harrier, the merlin, the peregrine, and the sparrow-hawk are still numerous. The short-eared owl is common, and various other species occasionally haunt the islands. The raven, the Royston crow, the rook, and the jackdaw are all met with. The red grouse, the golden plover, the dotterel plover, and the grey plover are abundant in some districts. The snipe, the woodcock, the common heron, the curlew, the little bittern, the white stork, the white spoonbill, the knot, the ruff, and the common coot frequent the more remote regions. There is an immense variety of water-fowl. Most of the singing birds found in Scotland are either natives or occasional visitants. The great skua gull still breeds in the island of Foula, where its eggs are carefully preserved.

Flora.—Although the Orkneys contain some plants which are rare in the British Isles, the flora of the group is much smaller in variety than that of the more mountainous Shetlands. For lists the reader is referred to the paper on the flora of the Orkneys by W. Irvine Fortescue, and that on the flora of Shetland by Dr Peter White, both contained in Tudor's *Orkneys and Shetland*, 1883.

Manufactures.—According to Barry the woollen manufacture was at one time of some importance in the Orkneys, but by the end of last century had been superseded by that of linen, introduced about 1747. For the manufacture flax was at one time largely grown. After the introduction of machinery in the south it was no longer possible to continue the manufacture with profit, and, although straw-plaiting for a time took its place, it also succumbed to southern competition. Next to the linen trade the most important industry in the 18th century was the manufacture of kelp, introduced in 1722. With the abolition of the duty on Spanish barilla the manufacture for a time suffered severely, but of late years it has revived and now yields about £1500 annually. It is, however, chiefly on agriculture that the Orkneys depend, and their rapid progress in this respect has been greatly facilitated by the very ample steam communication by three different routes with Scotland. Since 1871 telegraphic communication has extended to Unst, the most northerly of the Shetland group. Straw-plaiting is no longer practised in Shetland, but kelp-making is still carried on. The staple manufacture is knitted goods. According to Edmonston,

[1] Interesting information, not yet altogether out of date, on the agriculture of the Orkneys will be found in a paper by R. O. Pringle, and on that of the Shetlands in papers by H. Evershed and R. S. Skirving in the *Trans of the Highland and Agricultural Society*, 1874.

stockings to the value of about £17,000 were annually exported from Shetland about the beginning of the present century. The manufacture of gloves was introduced about 1800, of shawls about 1840, and of veils about 1850. Fair Island has long been famous for its coloured hosiery, into the art of knitting which the inhabitants are said to have been initiated by the wrecked mariners of one of the ships of the Spanish Armada; but this tradition is an extremely doubtful one.

Fisheries.—For some centuries the neighbourhood of the Orkneys and Shetlands was frequented by the fleet of Dutch vessels connected with the great herring fishery, but Barry states that fishing in his time was almost wholly neglected by the inhabitants of the Orkneys. The principal herring-stations are at Papa-Stronsay, Deersound, Holm, and South Ronaldshay. The greater part of the catch of spring herrings is despatched direct to Hamburg. The cod and ling fishing is prosecuted chiefly by the inhabitants of the north isles, both in open boats and in smacks, at the Faroes and near Iceland. Fishing is almost the sole occupation of the Shetland men, the women doing nearly all the farm-work and occupying also every spare moment in knitting both in the house and when carrying their burdens. The Shetland herring fishery has lately (1884) made rapid strides, but the increase in the take of herrings is partly due to boats from the south. As the herring fishery has increased, the deep-sea ling and cod fishing, formerly the mainstay of the islands, has proportionately diminished. The whole of the fisheries were originally in the hands of the Dutchmen, but in 1712 their supremacy was destroyed by the imposition of the duty on salt. Until within recent years the boats chiefly used were the old "sixerns" built in the islands after the model of the Norwegian yawl, but whole or half-decked boats are now rapidly taking their place. The total number of persons now employed in the fisheries of the Orkneys and Shetlands together is about 11,000, Shetland employing over 7430. The number of smacks belonging to the Orkneys is about 30, employing over 300 men; Shetland possesses about double this number, and the Shetland smacks are much more successful than those of Orkney, as more of them frequent the distant fishing-grounds. Shetland possesses, in addition to these, over 300 decked first-class and a large number of smaller fishing boats.

Administration and Population.—The islands of Orkney and of Shetland form one sheriffdom or stewartry, but the sheriff has a substitute in Orkney and another in Shetland. The county of Orkney and Shetland returns one member to parliament, and Kirkwall is included in the Wick district of burghs, which returns one member. Orkney includes 18 parishes and Shetland 12. From 24,445 in 1801 the population of Orkney had in 1831 increased to 28,847, and in 1861 to 32,395, but in 1881 was only 32,044, of whom 14,982 were males and 17,062 females. The population of Shetland in 1801 was 22,379, which had increased in 1831 to 29,392, and in 1861 to 31,670, but by 1881 had diminished to 29,705, of whom 12,656 were males and 17,049 females. In Orkney there were 113·88 females to every 100 males, but in Shetland the proportion is 134·71, by far the largest in any county of Scotland. The number of inhabited islands in Orkney was 29, the Mainland numbering 17,165 persons, while 5 other islands had a population of over 1000 each, viz., South Ronaldshay 2557, Westray 2200, Sanday 2082, Hoy 1380, and Stronsay 1274. Shetland comprised 30 inhabited islands, of which the Mainland contained 20,821, Yell 2529, and Unst 2173. In the Orkneys the only town is Kirkwall (3947), a royal and parliamentary burgh, and the villages are Stromness (1705) and St Margaret's Hope (412). Stromness, which received an independent charter in 1817, has risen within the last century from a mere fishing hamlet to a port of some importance. It possesses a fine natural harbour, with a pier accessible to vessels of large tonnage at high tides, and a patent slip. In the Shetlands Lerwick (4045) is the principal town, distant 272 miles from Edinburgh and 95 from Kirkwall. It dates from the beginning of the 17th century. Its harbour can afford safe accommodation for an immense fleet; and it is now the rendezvous of vessels for the whale fishery at Davis Straits and Greenland. Scalloway (648), the only village of the Shetlands, and the original capital, is situated on a fine bay about 6 miles west of Lerwick. It possesses the ruins of an ancient castle, and is the seat of a herring fishery.

History and Antiquities.—Scarcely any information is obtainable from Roman writers regarding the Orkneys, and none regarding the Shetlands, but there is abundant evidence that both groups of islands were originally inhabited by a Pictish population. Of the two forms of Picts' houses—chambered mounds and underground habitations or weems—many are still so entire as to afford an accurate notion of the character of the buildings; and of the barrows or burial-mounds, which number over 2000, the majority belong to the Pictish period. The rings of Brogar and Stenness are the only stone circles in the Orkneys, and there are only five groups in Shetland, three being in Unst and two in Fetlar. It has been disputed whether the fortresses known as borgs or brochs are to be attributed to the Picts or the Norsemen, but the balance of probability seems to indicate that they were erected before the Norse invasion, and in defence against the Northmen. Orkney possessed 70 and Shetland 75, the most perfect of existing specimens being the tower of Mousa in Shetland. Although few implements, and those of the rudest kind, have been discovered in the Picts' houses, the brochs contain handmills used for grinding corn, stone whorls and bone combs employed in woollen manufactures, and examples of a rude kind of pottery. Various scattered notices occur of early expeditions to the Orkneys, the most important being those of the Dalriadic Scots about the beginning of the 6th century; but the Picts soon regained their power, and the islands remained in their possession until the Norse invasions of the 9th century.

The earliest notice regarding the Christianization of the islands is that of a visit of Cormac and other companions of St Columba to the Orkneys about 565. The Irish monk Dicuil, writing about 825, states that a "certain honest monk had visited" certain islands "in the northern British seas," which are evidently identical with the Shetland Islands. Other proofs of the early Christianization of the Orkneys and Shetlands are the dedications to St Columba, St Bridget, St Ninian, and St Tredwell; the designation *Papa* applied to several of the islands, that being the Norse name for the Irish missionaries; monumental stones like those on the mainland of Scotland bearing the Ogham inscription, four having been found in Shetland and one in the broch of Burrian in North Ronaldshay in Orkney; the discovery of square-sided bells peculiar to the early ages of the church; and the occurrence of the crescent symbol on various sculptured slabs.

About the end of the 8th century the Orkneys and Shetlands became the rendezvous of the northern vikings, who sailed thence to ravage the coasts of Norway and the western coasts and islands of Scotland. About 872 the Norse settlement in the islands became perpetual by the flight to it of the jarls, dispossessed of their authority by Harold Haarfager. As the jarls began a retaliatory warfare on the coasts of Norway, Harold fitted out a great expedition against them, and placed the Orkneys and Shetlands under the government of Rognvald, earl of Mœri, who, with the permission of Harold, handed it over to his brother Sigurd. Guttorm succeeded his father Sigurd, but, dying childless about a year afterwards, was succeeded by Hallad, son of Rognvald, who, being unable to cope with the vikings, returned to Norway, Einar, another son of Rognvald, taking his place. He thoroughly subdued the vikings, and also taught the inhabitants to use peat for fuel, from which he received the name of Torf Einar. The two eldest sons of Einar were slain in battle in England, and the third, Thorfinn Hausakliuf, who succeeded in 950, having married Grelauga, daughter of Duncan, earl of Duncansby, became joint-earl of Orkney and Caithness. Thorfinn had five sons, all of whom were shortly afterwards slain, except the youngest, Hlodver. He was succeeded, about 980, by Sigurd the Stout, who fought against the Scots, but ultimately came to an agreement with Malcolm, king of the Scots, whose daughter he obtained in marriage. Sigurd was slain in a great battle at Clontarf against Brian Boroime, king of Munster, in 1014, upon which King Malcolm of Scotland bestowed the earldom of Caithness on Thorfinn, a son of Sigurd by his daughter, the earldom of the islands being divided among Somerled, Brusi, and Einar, Sigurd's sons by a former marriage. After the death of Somerled and Einar the claim of Brusi to the earldom of the islands was disputed by Thorfinn. An arrangement was finally made that Thorfinn should receive two-thirds of the islands; but on the death of Brusi he took possession of all the islands; he came to an agreement, however, with Rognvald Brusison which lasted for eight years, when Thorfinn, having defeated Rognvald in a sea-fight in the Pentland Firth, took possession of the earldom also. Finally he obtained recognition from the king of Norway, and, after making a pilgrimage to Rome, built Christ's Church in Birsay, where he established a bishop's see. Thorfinn was succeeded, about 1064, by his two sons Paul and Erlend, whom King Magnus (Barefoot) of Norway subsequently replaced by his son Sigurd. He, on his father's death, became king of Norway, and was succeeded in the earldom of the Orkneys by Hakon, Paul's son, and Magnus, Erlend's son, the latter of whom was murdered by the former in 1115. Hakon was succeeded by his two sons Harold and Paul, the former of whom shortly afterwards died, when Kali, a nobleman of Norway, receiving from King Sigurd the gift of half of the Orkneys, surprised Paul and induced him to consent to this arrangement, whereupon, in accordance with a vow he had made, he built a "stone minster" at Kirkwall. Paul was carried off by the vikings, and his place as joint-earl was taken by Harold, the son of Maddad, earl of Athole. King Eystein superseded Harold by Erlend, son of Harold the son of Hakon. Erlend fortified himself against Harold in the broch of Mousa in Shetland, until Harold came to an agreement with him. Afterwards Erlend was slain in a battle with Harold and Rognvald, who then reigned jointly till the death of Rognvald in 1158. On account of Harold's support of Sigurd, son of Magnus Erlingson, against King Sverri of Norway, he was deprived of the whole of Shetland. He was succeeded in 1206 by his sons John and David, the former of whom, on the death of his brother seven years afterwards, became sole ruler. He was slain in an inn in Thurso in 1231, and, as the line of

Norse earls became with him extinct, the earldom of Caithness was granted to Magnus, second son of Gilbride, earl of Angus, who was apparently confirmed in the earldom by the king of Norway. About 1321 the earldom passed from the Angus to the Strathearn line, and about 1379 to Henry St Clair, who erected the castle of Kirkwall. In 1468 the Orkneys and Shetlands were pledged by Christian I. of Denmark for the payment of the dowry of his daughter Margaret, betrothed to James III. of Scotland, and, as the money was never paid, their connexion with the crown of Scotland became perpetual. In 1471 King James III. bestowed the castle and lands of Ravenscraig in Fife on William, earl of Orkney, in exchange for all his rights to the earldom of Orkney, and an Act of Parliament was passed 20th February of the same year annexing the earldom of Orkney and Shetland to the Scottish crown.

In 1540 Kirkwall was visited by James V. In 1564 Lord Robert Stewart, natural son of James V., was made sheriff of the Orkneys and Shetlands, and received possession of the estates of the udallers; in 1581 he was created earl of Orkney by James VI., the charter being ratified in 1591 to his son Patrick. In 1615 the earldom was again annexed to the crown. The islands were made the rendezvous of the disastrous expedition of Montrose in 1650. During the Protectorate the Orkneys were visited by a detachment of Cromwell's troops, who initiated the inhabitants into various industrial arts and new methods of agriculture. In 1707 the islands were granted to the earl of Morton in mortgage, redeemable by the crown on payment of £30,000, and subject to an annual feu-duty of £500; but in 1766 his estates were sold to Sir Lawrence Dundas, ancestor of the earls of Zetland.

Among the relics of the Norse settlement in the islands the most remarkable are the inscriptions on the great sepulchral cairn of Maeshow, the Orkahaug of the saga, which was, however, itself of Pictish origin. The topography, both of Orkney and of Shetland, is altogether Norse, and, although the influx of Scottish settlers gradually extinguished the old Norse tongue, many of the Norse names still linger, and even a form of the old odal succession and mode of land tenure still survives. Norse was generally spoken in the islands in the 16th century; and, according to Barry, in Orkney as late as the end of the 17th century it continued to be spoken in four parishes in the Mainland by the people in their own houses; but within his recollection it was almost entirely extinct, except in one parish in the heart of the Mainland. In Shetland it continued to be spoken much longer, and Low, during his tour in 1774, found the Norse language in Foula, "but much worn out." He states that it was the language of the last age, and he gives several specimens, including the Lord's Prayer and an old ballad (Low's *Tour*, pp. 105-112). The Shetlanders are still of almost unmixed Norse lineage, and words and phrases of Norse origin still tinge their dialect. Low describes a monument with Runic inscriptions in the churchyard of Crosskirk, Northmavine; and a Runic fragment found at Aith's Voe, Cunningsburgh, Shetland, is now in the museum of the (Scottish) Society of Antiquaries. Broken swords and fragments of shield-bosses have been dug up in many places, and also many of the peculiar brooches buried as relics in the graves of the Norse women during the Pagan period. At Birsay are remains of an old palace of the jarls.

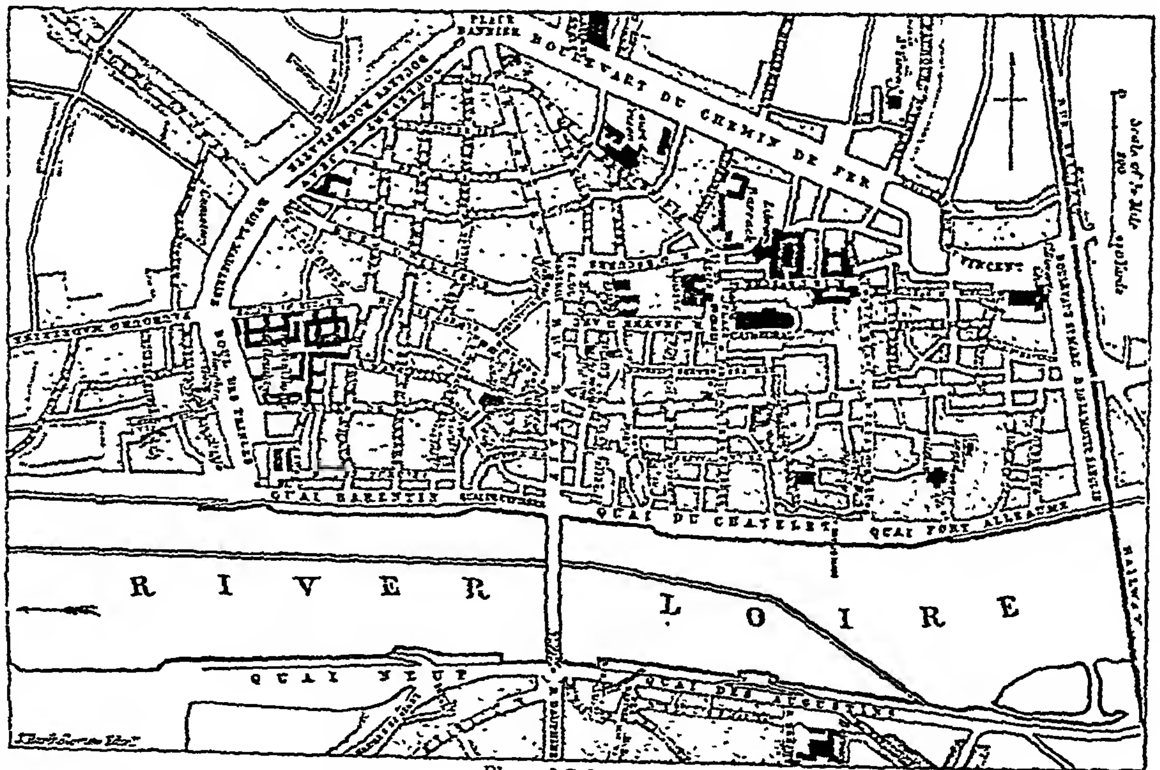
In early times both the archbishop of Hamburg and the archbishop of York disputed with the Norwegians ecclesiastical jurisdiction over the Orkneys and the right of consecrating bishops; but ultimately the Norwegian bishops, the first of whom was William the Old, consecrated in 1102, continued the canonical succession. The see remained vacant from 1580 to 1605, and from 1638 till the Restoration; and, after the accession of William III., episcopacy was in 1697 finally abolished, although many of the clergy refused to conform. Besides the cathedral-church of KIRKWALL (*q.v.*), the most interesting of the old churches are Egilshay church, built about the beginning of the 12th century, and possessing a round tower; the ruins of the circular church at Orphir; the remains of Christ Church, Birsay, built by Earl Thorfinn in the 11th century; the chapel of Weir, supposed to have been built in the 12th century; St Peter's Church, Birsay; and the remains of a chapel on the brough of Deerness. In Shetland there were at one time three towered churches—St Lawrence in Burra, St Magnus at Tingwall, and Ireland in Dunrossness; but of these there are now no remains. There are ruins of an old cruciform church at Culbinsbrough, of an old Norse church dedicated to St Olaf at Papil, and of various chapels in several of the islands.

The earliest written record on the Orkneys and Shetlands is *The Orkneyinga Saga*, an edition of which, with notes by Joseph Anderson, appeared in 1873. Next in antiquity is John the Benedictine's *Descriptio Insularum Orchadiarum*, 1529. Several works on both groups were written during last century, or about the beginning of the present, including Wallace, *Account of the Islands of Orkney*, 1700; Brand, *Brief Description of Orkney, Zetland, &c.*, 1701; Gifford, *Description of the Zetland Islands in 1733*, published in 1879; Low, *Tour through the Islands of Orkney and Schetland in 1774*, published in 1879; Barry, *History of the Orkney Islands*, 1805; Edmonston, *Zetland Islands*, 1809; and Shirreff, *General View of the Agriculture of the Orkney and Shetland Islands*, 1814. On the natural history there have been published—Low, *Fauna Orcadensis*, 1813; Baikie and Heddle, *Historia Naturalis Orcadensis*, part i., 1848; and Crichton, *A Naturalist's Ramble to the Orcades*, 1866. See also Gorrie, *Summers and Winters in the Orkneys*, 1868; Hibbert, *Description of the Shetland Isles*, 1822; Bell, *Art Rambles in Shetland*, 1869; Cowie, *Shetland*, 1874-80; Tudor, *Orkneys and Shetland; their Past and Present State*, 1883; and Fea, *Shetland and its Inhabitants*, 1884. (T. F. H.)

ORLEANS, a city of France, chief town of the department of Loiret, lies on the right bank of the Loire, 75 miles south-south-west of Paris. At Les Aubrais, a mile to the north, is one of the chief railway junctions in the country. Besides the Paris and Orleans Railway, which there divides into two main lines—a western to Nantes and Bordeaux *via* Tours, and a southern to Bourges and Toulouse *via* Vierzon—branches leave Les Aubrais eastwards for Pithiviers, Châlons-sur-Marne, and Gien, northwest for Châteaudun and Rouen. The whole town of Orleans is clustered together on the right bank of the river and surrounded by fine boulevards, beyond which it sends out suburbs along the various roads. With the suburb of St Marceau on the left bank it is connected by a handsome stone bridge (1092 feet long and 51 feet wide) of nine arches, erected in the 18th century. Farther up is the railway bridge. The river is canalized on the right, and serves as a continuation of the Orleans Canal, which unites the Loire with the Seine by the canal of the Loing. Owing to its position on the northmost point of the Loire Orleans has long been the centre of communication between the Loire basin and Paris. Wines, grain, wool, and trees for planting are the main products of the surrounding districts and the commercial staples of the city, which, while devoted rather to trade than to manufactures, has establishments for the making of vinegar, blankets, hosiery, worsted, the so-called Rheims biscuits, confectionery, preserved foods, pins, pottery, boilers, paper, cardboard, soap, and dressed skins. The chief interest of the place, however, lies in its public buildings and the historical events of which it has been the scene. Proceeding from the railway station to the bridge over the Loire, the visitor crosses Orleans from north to south and passes through the Place du Martroi, the heart of the city. In the middle of the square stands an equestrian statue of Joan of Arc, 30 feet high, in bronze, resting on a granite pedestal surrounded by bas-reliefs representing the leading episodes in the life of the heroine. In 1855 it took the place of an older statue executed in the beginning of the century, which was then transferred to the left bank of the Loire at the end of the bridge, a few paces from the spot where a simple cross marks the site of the *Fort des Tournelles* captured by Joan of Arc on 7th May 1429. From the Place du Martroi, the Rue Jeanne d'Arc leads to the cathedral of Ste Croix. This church, commenced in 1287, was burned by the Huguenots in 1567 before its completion. Henry IV., in 1601, laid the first stone of the new structure, the building of which has continued until now. It is a Gothic cathedral on a large scale, consisting of a vestibule, a nave with double aisles, a corresponding choir, a transept, and an apse. Its length is 482 feet, its greatest width 206, and the height of the central vaults 108 feet. The west front has two flat-topped towers each of three stories, of which the first is square, the second octagonal, and the third cylindrical. The whole front is Gothic, but was designed and constructed in the 18th century and exhibits all the defects of the period. A central spire 328 feet high, on the other hand, raised about twenty-five years ago, recalls the pure ogival style of the 13th century. In the interior the choir chapels and the apse, dating from the original erection of the building, are worthy of note. In the episcopal palace and the great seminary are several remarkable pictures and pieces of wood-carving; and the latter building has a crypt which some antiquaries hold to belong to the 6th century. The church of St Aignan, said to have been founded by the son of Constantine, and often rebuilt, contains in a gilded and carved wooden shrine the remains of its patron saint, who occupied the

see of Orleans at the time of Attila's invasion. The crypt dates from the reign of Robert the Pious (the beginning of the 11th century). The once beautiful sculpture of the exterior has been altogether ruined; the interior has been restored, but not in keeping with the original style. A third church, St Euverte, consecrated to one of the oldest bishops of Orleans (*ob.* 391), is an early Gothic building dating from the 12th century. To the west of Rue Royale stand the church of St Paul, whose *façade* and isolated tower both bear fine features of Renaissance work, and Notre Dame de Recouvrance, rebuilt between 1517 and 1519 in the Renaissance style and dedicated to the memory of the deliverance of the city. The Hôtel de Ville, built in 1530, was formerly the residence of the governors of Orleans, and was occupied by the kings and queens of France from Francis II. to Henry IV. The front of the building, with its different coloured bricks, its balconies supported by caryatides attributed to Jean Goujon, its gable-ends, and its windows, recalls the Flemish style. There are several niches with statues. Beneath, between the double flight of steps leading up to the entrance, stands a bronze reproduction of the statue of Joan of Arc, a masterpiece of the princess Mary of Orleans, which is preserved in the Versailles museum. The richly-decorated apartments of the first story contain paintings, interesting chimneys, and a bronze statuette (also by the princess Mary) representing Joan of Arc mounted on a caparisoned horse and clothed in the garb of the knights of the 15th century. The great hall in which it is placed also possesses a copy of Ingres's picture, "Joan of Arc at the Consecration of Charles VII.," and a plaster model of the Bigot tower at Rouen, where the heroine was imprisoned; the chimney is decorated with three bas-reliefs of Domremy, Orleans, and Rheims, all associated with her life. The historical museum at Orleans is one of the most interesting of provincial collections; a special section consists of all the objects—tapestries, banners, pictures, statuettes—relating to Joan, as well as of arms or bullets found on the battle-field of Patay; and the numismatic, mediæval, and Renaissance departments, and the collection of ancient vases, are all of great value. The city also possesses a separate picture gallery, a sculpture gallery, a natural history museum, and four learned societies. The public library (50,000 volumes) comprises among its manuscripts a number dating from the 7th century, and obtained in most cases from St Benoît on the Loire. At Orleans the general hospital has incorporated the almshouse for the aged, the orphan asylum, the lunatic asylum, the Hôtel Dieu, the maternity hospital, and the preparatory school of medicine and pharmacy. It is one of the finest institutions in France. In the corn-exchange is embodied a vast cloister formed by 16th-century arcades, once belonging to the old cemetery. Among the private houses those of Agnes Sorel and Francis I., and that occupied by Joan of Arc during the siege of 1429, are of historical interest. The "White Tower" is the last representative of the towers rendered famous by that siege. Near the Quai du Châtelet a stretch of wall, dating at least from the 9th century, was discovered some years ago; it is supposed to be a portion of the *châtelet* or *tête du pont* of the Roman period. A statue has been erected in front of the town-house to the jurisconsult Pothier, one of the most illustrious of the natives of Orleans. The anniversary of Joan of Arc is celebrated every year with great pomp. After the English had raised the siege the popular enthusiasm improvised a procession, which marched with singing of hymns to the cathedral of St Paul; and the ceremony is still repeated on the first days of May by the clergy and the civil and military functionaries. The population of Orleans is 57,264.

Whether Genabum is to be identified with Orleans or with Gien is matter of dispute; but Aurelianum appears as a flourishing town in the 5th century. St Aignan (as already mentioned) was bishop when, in 451, it was vainly besieged by Attila. Clovis got possession of the city in 498, and in 511 held there the first council assembled in



Plan of Orleans.

France. Though the dignity which it then obtained, of being the capital of a separate kingdom, was lost by its union with that of Paris in 613, Orleans remained during all the mediæval period one of the first cities of the French monarchy; several of the kings dwelt within its walls, or were consecrated in its cathedral; it had a royal mint, was the seat of councils, and obtained for its schools the name of university (1305), and for its soldiery an equal standing with those of Paris. It became the apanage of one of the first princes of the blood under Philip of Valois, who made it a duchy for his second son, and under Charles VI., who bestowed the duchy on his brother Louis. After the assassination of this last prince by Jean sans Peur, duke of Burgundy (1407), the people of Orleans sided resolutely with the Armagnacs, and in this way brought upon themselves the attacks of the Burgundians and the English. Joan of Arc, having entered the beleaguered city on 29th April 1429, effected the raising of the siege by 7th May by means of an attack on the Fort des Tournelles, in the course of which she was wounded. After the Amboise conspiracy (1560) the States-General were convoked at Orleans, where Francis II. died. In 1562 it became the headquarters of Condé, the Protestant com-

mander-in-chief, and the duke of Guise was assassinated on his way to besiege it. Huguenot and Leaguer were alternately in possession till Henry IV. came in person to take it in 1594. The duchy of Orleans, united to the crown by Louis XII., was again detached in favour of Gaston, brother of Louis XIII., and afterwards for Philip, brother of Louis XIV. and founder of the present house of Orleans. Since 1789 the title "duke of Orleans" has been purely honorary. During the Revolution the city suffered from the sanguinary excesses of Barère and Collot d'Herbois. It was occupied by the Prussians in 1815 and in 1870. As the centre of the preparations made by the Government of the National Defence for raising the siege of Paris, it bore the brunt of numerous battles fought in its vicinity, and of the hostile occupation to which they led.

ORLEANS, CHARLES, DUKE OF (1391-1465), commonly called Charles d'Orléans, was the eldest son of Louis, duke of Orleans (brother of Charles VI. of France), and of Valentina Visconti, daughter of Galeaso of Milan. He was born on 26th May 1391. Although many minor details are preserved of his youth, nothing except his reception in 1403, from his uncle the king, of a pension of 12,000 livres d'or is worth noticing, until his marriage three years later (29th June 1406) with Isabella, his cousin, widow of Richard II. of England. The bride was two years older than her husband, and is thought to have married him unwillingly, but she brought him a great dowry,—it is said, 500,000 francs. She died three years later, leaving Charles a widower and father of a daughter at the age of eighteen. He was already duke of Orleans, for Louis had been assassinated by the Burgundians two years before (1407). He soon saw himself the most important person in France, except the dukes of Burgundy and Brittany, the king being a cipher. This position his natural temperament by no means qualified him to fill. His mother was eager for vengeance for her husband, and for years Charles did his best to carry out her wishes by filling France with intestine war. Of this, however, he was only nominally one of the leaders, the real guidance of his party resting with the great count of Armagnac, whose daughter, Bonne, he married, or at least formally espoused, in 1410. Five years of confused negotiations, plots, and fightings passed before the English invasion and the battle of Agincourt, where Charles was joint commander-in-chief. According to one account he was dangerously wounded and narrowly escaped with his life. He was certainly taken prisoner and carried to England, which country was his residence thenceforward for a full quarter of a century. Windsor, Pontefract, Ampthill, Wingfield (Suffolk), and the Tower are named among other places as the scenes of his captivity, which, however, was anything but a rigorous one. He was maintained in the state due not merely to one of the greatest nobles of France but to one who ranked high in the order of succession to the crown. He hunted and hawked and enjoyed society amply, though the very dignities which secured him these privileges made his ransom high, and his release difficult to arrange. Above all, he had leisure to devote himself to literary work. But for this he would hardly be remembered as anything better than a more than usually amiable and less than usually able example of the higher feudal nobility, whose political position rather than their personal faults made government difficult or impossible in the later Middle Ages.

The work which secures a measure of immortality to Charles d'Orléans consists wholly of short poems in the peculiar artificial metres which had become fashionable in France about half a century or more before his birth, and which continued to be fashionable till nearly a century after his death. Besides these a certain number of English poems have been attributed to him. It is certain that he studied the language of his captors, but it is more than doubtful whether the extant English poems which bear his name are genuine, and in any case they are of no value. The ingenuity of a single English critic has striven to attribute to him a curious book in prose, called *Le Débat des Hérauts de France et d'Angleterre*, but M. Paul Meyer, in his edition of the book in question, has completely disposed of this theory. For all practical purposes, therefore, Charles's work consists of some hundreds of short poems, a few in various metres, but the majority either ballades or rondels. The chronology of these poems is not always clear, still less the identity of the persons to whom they are addressed, and it is certain that some, perhaps the greater part of them, belong to the later years of the poet's life. But many are expressly stated in the manuscripts to have been "composed in prison," others are obviously so composed, and, on the whole, there is in them a remarkable unity of literary flavour. Charles d'Orléans is not distinguished by any extraordinary strength of passion or originality of character; but he is only the more valuable as the last and not the least accomplished representative of the poetry of the middle of the Middle Ages, in which the form was almost everything, and the personality of the poet, save in rare instances, nothing. Yet Charles d'Orléans is not entirely without *differentia*. If he were he would hardly hold the place which at present he justly occupies. He is a capital example of the cultivated and refined—it may almost be called the lettered—chivalry of the last chivalrous age, expert to the utmost degree in carrying out the traditional details of a graceful convention in love and literature. But he is more than this; in a certain easy grace and truth of expression, as well as in a peculiar mixture of melancholy, which is not incompatible with the enjoyment of the pleasures, even the trifling pleasures, of life, with listlessness that is fully able to occupy itself about those trifles, he stands quite alone. He has the urbanity of the 18th century without its vicious and prosaic frivolity, the poetry of the Middle Ages without their tendency to tediousness. His best-known rondels—those on Spring, on the Harbingers of Summer, and others—rank second to nothing of their kind.

Poetry, however, could hardly be an entire consolation, and it is not surprising to find that Charles, during all the long years of his captivity, was perpetually scheming for liberty. But the English Government had too many reasons for keeping him, and it was not till his hereditary foe Philip the Good of Burgundy interested himself in him that the Government of Henry VI., which had by that time lost most of its hold on France, released him in return for an immediate payment of 80,000 *saluts d'or*, and an engagement on his part to pay 140,000 crowns at a future time. The agreement was concluded on 2d July 1440. He was actually released on 3d November following, and almost immediately cemented his friendship with Duke Philip by marrying his niece, Mary of Cleves, who brought him a considerable dowry to assist the payment of his ransom. He had, however, some difficulty in making up the balance, as well as the large sum required for his brother, Jean d'Angoulême, who also was an English prisoner. The last twenty-five years of his life (for, curiously enough, it divides itself into three almost exactly equal periods, each of that length) were spent partly in negotiating, with a little fighting intermixed, for the purpose of gaining the Italian county of Asti, on which he had claims through his mother, partly in travelling about, but chiefly at his principal seat of Blois. Here he kept a miniature court which, from the literary point of view at

least, was not devoid of brilliancy. At this most of the best-known French men-of-letters at the time—Villon, Olivier de la Marche, Chastelain, Meschinot, and others —were residents or visitors or correspondents. His son, afterwards Louis XII., was not born till 1462, three years before Charles's own death. He had become, notwithstanding his high position, something of a nullity in politics, and tradition ascribes his death to vexation at the harshness with which Louis XI. rejected his attempt to mediate on behalf of the duke of Brittany. At any rate he died, on 4th January 1465, at Amboise. Many of his later poems are small occasional pieces addressed to his courtiers and companions, and in not a few cases answers to them by those to whom they were addressed exist. The best edition of Charles d'Orléans's poems, with a brief but sufficient account of his life, is that of C. d'Héricault in the *Nouvelle Collection Jannet*, Paris, 1874. (G. SA.)

ORLEANS, DUKES OF. The title duke of Orleans was borne by three distinct dynasties of French princes of the blood. The first duke of Orleans was LOUIS (1371-1407), second son of King Charles V., who was born in 1371, and received the title from his brother Charles VI. in 1392. Both he and his son and heir played very important parts in the history of the Hundred Years' War with England (see FRANCE) in opposition to the duke of Burgundy. He had been appointed regent of France during the madness of his brother, Charles VI., and had, by his immorality and his intimacy with the queen, raised a great scandal throughout the kingdom. The duke of Burgundy made himself the mouthpiece of the general discontent, and on 23d November 1407 had the regent murdered in the streets of Paris in revenge for his own father's death. Louis's son CHARLES is the subject of the preceding article. With his son's accession to the throne as Louis XII. the dukedom of Orleans merged in the crown. It was revived in 1626, when Louis XIII. created his brother, JEAN BAPTISTE GASTON (1608-1660), the third son of Henry IV., duke of Orleans and Chartres and count of Blois. Gaston of Orleans's fruitless intrigues fill the history of France from the time of Richelieu and Mary de' Medici to that of Mazarin and Anne of Austria. Four times he was banished from France, and more than four times did he sacrifice his associates, who had plotted the overthrow of Richelieu. To him Montmorency, Cinq-Mars, and De Thou owed their deaths, and he was only protected from sharing their fate by the fact of his royal birth. On the death of Louis XIII. he was appointed lieutenant-general of the kingdom for the minority of Louis XIV. But Mazarin never meant him to exercise any real power, and when he became convinced that his power was subordinate to the cardinal's he entered the ranks of the Fronde (see MAZARIN), in which he played a conspicuous part, but always as the tool or the mouthpiece of others. Far more manly and determined was his daughter, best known as La Grande Mademoiselle, who with her own hands directed the guns of the Bastille upon Turenne's soldiers on the day of the battle of St Antoine. He was afterwards exiled to his castle of Blois, where he died without male issue in 1660. The title was at once revived by Louis XIV., who created his brother PHILIPPE (1640-1701) duke of Orleans and of Chartres, and married him to Henrietta, the sister of Charles II. of England. The court was soon entertained by the details of the quarrels between the duke and duchess, and by the former's jealousy even of his brother the king, and, when Henrietta, after successfully detaching Charles from the Triple Alliance and negotiating the treaty of Dover, died suddenly in 1670, the duke was universally accused of poisoning her. In the following year he married Princess Charlotte Elizabeth of Bavaria. In the campaign of 1677 he so distinguished himself that Louis XIV. became afraid of his popularity and refused to allow him to go again to the frontier. He was obliged to waste his time at Paris like other noblemen, in attendance on the court, until his death in 1701. He left one son and three daughters: the daughters married Charles II. of Spain, Victor Amadeus II. of Savoy, and Prince Charles of Lorraine; the son was PHILIPPE (1674-1723), the regent, who has been spoken of in FRANCE, vol. ix. p. 584. Before succeeding to the dukedom of Orleans in 1701 he had given no indication of political ambition or capacity, yet Louis XIV. distrusted him, and thought to mar his chance of allying himself with any royal or noble family, and to unite his interest with that of his own natural children, by marrying him to his illegitimate daughter by Madame de Montespan, Mademoiselle de Blois. This distrust was increased as the king's legitimate descendants died off, and in his will he left his natural son, the duke of Maine, guardian of the person of his great-grandson and heir, and greatly circumscribed the authority of Orleans as regent. On the death of the grand monarque in 1715 Philippe, guided by the advice of the duke of Saint Simon, induced the parliament of Paris to upset the will and make him regent of the realm with the fullest authority. By the same nobleman's advice he procured the degradation of the natural children of the late king from the precedence above the peers of France which had been conferred on them. Saint Simon hoped he would go yet further, and that he would entrust the nobility with their old political authority; but the regent had no mind to restore the privileges which Richelieu had had so much difficulty in combating, and which the policy of Louis XIV. had only, after long years, been able to destroy. He determined to hand down to Louis XV. the absolute power of his great-grandfather. Another main object he sought was to keep France at peace, which alone could restore her to her former prosperity. With this intention he joined the Quadruple Alliance. He remained in close union with Stanhope, the prime minister of England, and the emperor, whilst Dubois worked out his intentions. This alliance enabled the kingdoms of England and France to overthrow Alberoni and prevent his disturbing the peace of Europe. In compliance with the wishes of Lord Stair, the able English ambassador, Orleans expelled the Pretender from France, and was helped to overthrow the conspiracy of Cellamare—the French part of Alberoni's scheme by which the bastards of Louis XIV. were to overthrow the regent. Under this peaceful policy France rapidly began to recover prosperity, and Philippe hoped to restore the condition of her finances by listening to the advice of a Scotch adventurer, and buying out the farmers-general of the taxes, who were the real causes of the financial distress (see LAW, JOHN, vol. xiv. p. 367). It should also be noted that the regent showed both courage and determination in putting a stop to the insane speculations of the Rue Quincampoix. He cannot be called a great statesman; he indeed formed great plans, but left all details of government to Dubois. Yet his real political ability must not be overlooked, as is often done, because the period of the regency is only regarded, as a rule, as a period of wild debauchery, in which the regent ruled a court of bacchanals. Philippe never allowed his pleasures to interfere with his politics. His fidelity to the youthful monarch is no less remarkable in a man of his seemingly abandoned character, hence it is no wonder that when Louis XV. attained his majority he maintained the duke of Orleans and with him Dubois in power. But a career of debauchery had weakened his physical powers, and, in the very year in which his ward had thus shown his gratitude to him (1723), he died. His character is best painted in an apologue of his mother's. "The fairies were all invited to my bedside, and

each giving my son one talent, he had them all. Unhappily an old fairy had been forgotten, who, on arriving after the others, exclaimed. 'He will have all the talents, excepting that of making good use of them.'"

The son of the regent, Louis (1703-1752), who succeeded him as duke of Orleans, played no part in politics, though his name frequently occurs in the social history of the time, and fills a great place in contemporary memoirs. Louis's son, Louis Philippe (1725-1785), was equally averse to politics, though he served as a soldier at the battle of Dettingen; his great delight was the theatre, and his place is rather in the history of the Paris green-rooms than in the history of France. But to Louis Philippe Joseph (1747-1793), son of the preceding, a more adventurous life was allotted, and his part in the history of the French Revolution is one of the most difficult problems to solve of that exciting period. He was born at St Cloud in 1747, and bore the title of duke of Montpensier until his grandfather's death in 1752. He then became duke of Chartres, and in 1769 married Louise Marie Adelaide de Bourbon Penthièvre, only daughter and heiress of the duke of Penthièvre, grand admiral of France, and the richest heiress of the time. Her wealth made it certain that he would be the richest man in France, and he determined to play a part equal to that of his great-grandfather, the regent, whom he resembled in character and debauchery. As duke of Chartres he opposed the plans of Maupeou in 1771, and was promptly exiled to his country estate of Villers-Cotterets (Aisne). When Louis XVI. came to the throne in 1774 Chartres still found himself looked on coldly at court; Marie Antoinette hated him, and envied him for his wealth, wit, and freedom from etiquette, and he was not slow to return her hatred with scorn. In 1778 he served in the squadron of D'Orvilliers, and was present in the naval battle of Ushant. He hoped to see further service, but the queen was opposed to this, and he was removed from the navy, and given the honorary post of colonel general of hussars. He then abandoned himself to pleasure; he often visited London, and became an intimate friend of the prince of Wales (afterwards George IV.); he brought to Paris the "anglomania," as it was called, and made jockeys as fashionable as they were in England. He also made himself very popular in Paris by his large gifts to the poor in time of famine, and by throwing open the gardens of the Palais Royal to the people. Before the meeting of the notables in 1787 he had succeeded his father as duke of Orleans, and showed his liberal ideas, which were largely learnt in England, so boldly that he was believed to be aiming at becoming constitutional king of France. In November he again showed his liberalism in the *lit de justice*, which Brienne had made the king hold, and was again exiled to Villers-Cotterets. The approaching convocation of the States-General made his friends very active on his behalf; he circulated in every *bailliage* the pamphlets which Sieyès had drawn up at his request, and was elected in three—by the noblesse of Paris, Villers-Cotterets, and Crépy-en-Valois. In the estate of the nobility he headed the liberal minority under the guidance of Adrien Duport, and led the minority of forty-seven noblemen who seceded from their own estate (June 1789) and joined the Tiers Etat. The part he played during the summer of 1789 is one of the most debated points in the history of the Revolution. The court accused him of being at the bottom of every popular movement, and saw the "gold of Orleans" as the cause of the Réveillon riot and the taking of the Bastille, as the republicans later saw the "gold of Pitt" in every germ of opposition to themselves There can be no doubt that he hated the queen, and bitterly resented his long court disgrace, and also that he sincerely wished for a thorough reform of the government and the establishment of some such constitution as that of England; and no doubt such friends as Adrien Duport and Choderlos de Laclos, for their own reasons, wished to see him king of France. The best testimony for the behaviour of Orleans during this summer is the testimony of an English lady, Mrs Grace Dalrymple Elliott, who shared his heart with Comtesse de Buffon, and from which it is absolutely certain that at the time of the riot of 12th July he was on a fishing excursion, and was rudely treated by the king on the next day when going to offer him his services. He indeed became so disgusted with the false position of a pretender to the crown, into which he was being forced, that he wished to go to America, but, as Comtesse de Buffon would not go with him, he decided to remain in Paris. He was again accused, unjustly, of having caused the march of the women to Versailles on 5th October. La Fayette, jealous of his popularity, persuaded the king to send the duke to England on a mission, and thus get him out of France, and he accordingly remained in England from October 1789 to July 1790. On 7th July he took his seat in the Assembly, and on 2d October both he and Mirabeau were declared by the Assembly entirely free of any complicity in the events of October. He now tried to keep himself as much out of the political world as possible, but in vain, for the court would suspect him, and his friends would talk about his being king. The best proof of his not being ambitious of such a doubtful piece of preferment is that he made no attempt to get himself made king, regent, or lieutenant-general of the kingdom at the time of the flight to Varennes in June 1791. He, on the contrary, again tried to make his peace with the court in January 1792, but he was so insulted that he was not encouraged to sacrifice himself for the sake of the king and queen, who persisted in remembering all old enmities in their time of trouble. In the summer of 1792 he was present for a short time with the army of the north, with his two sons, the duke of Chartres and the duke of Montpensier, but had returned to Paris before 10th August. After that day he underwent great personal risk in saving fugitives; in particular, he saved the life of the count of Champcenetz, the governor of the Tuileries, who was his personal enemy, at the request of Mrs Elliott. It was impossible for him to recede, and, after accepting the title of Citoyen Égalité, conferred on him by the commune of Paris, he was elected twentieth and last deputy for Paris to the Convention. In that body he sat as quietly as he had done in the National Assembly, but on the occasion of the king's trial he had to speak, and then only to give his vote for the death of Louis. His compliance did not save him from suspicion, which was especially aroused by the friendship of his eldest son, the duke of Chartres, with Dumouriez, and when the news of the desertion of Chartres with Dumouriez became known at Paris all the Bourbons left in France, including Égalité, were ordered to be arrested on 5th April. In prison he remained till the month of October, when the Reign of Terror began. He was naturally the very sort of victim wanted, and he was decreed "of accusation" on 3d October. He was tried on 6th November and was guillotined on the same day, with a smile upon his lips and without any appearance of fear. No man ever was more blamed than Orleans during the Revolution, but the faults of ambition and intrigue were his friends', not his: it was his friends who wished him to be on the throne. Personally he possessed the charming manners of a polished grand seigneur: debauched and cynical but never rude or cruel, full of gentle consideration for all about him but selfish in his pursuit of pleasure, he has had to bear a heavy load of blame, but it is ridiculous to describe the idle and courteous voluptuary as being a dark and designing scoundrel, capable of murder if it would serve his ambition. The execution of Philippe Égalité made the friend of Dumouriez, who was living in exile, duke of Orleans. Louis Philippe (1773-1850) was known as duke of Orleans throughout his long emigration and under the Restoration, and as duke of Orleans he was called upon to become king of the French in 1830. His eldest son, Ferdinand Louis Philippe Charles Henri (1810-1842), at once took the title of duke of Orleans. He was a brave soldier, and served in Algeria from 1834 to 1836. In 1837 he married Princess Helena of Mecklenburg, and became the father of the count of Paris, who is therefore *de jure* duke of Orleans. In 1839 he again went to Algeria, but the fatigues of the campaign were too much for him. He died at Neuilly in 1842. With him died the last duke of Orleans, for his son will not take the title; but the whole party which supports him is rightly known as the Orleanist party.

The chief authorities on the three most important dukes of Orleans are:—for Gaston of Orleans, Avenel's *Lettres de Richelieu, &c.*; Chéruel, *Correspondance de Mazarin*; Id., *Histoire de France pendant la minorité de Louis XIV.*; Id., *Histoire de France pendant le ministère de Mazarin*; for the regent Orleans, the portions of Michelet's and Martin's *Histories of France*; and for Philippe Égalité, Baschet's *Histoire de Philippe Égalité*, and the *Journal* of Mrs Grace Dalrymple Elliott (1859). (H. M. S.)

ORME, Robert (1728-1801), author of a *History of British India*, was the son of John Orme, surgeon in Bombay, and was born at Anjengo, Travancore, in June 1728 He was sent to Harrow school in 1736, and in 1742 to a school near London to obtain an education preparing him for commercial pursuits. In 1744 he became a clerk in the East India Company's service in Calcutta. In 1752 he went to Madras, and in the following year he returned home with Lord Clive, with whom he lived on terms of close intimacy. His knowledge of Indian affairs gave him considerable influence with the company. Returning to Madras in 1755, he was appointed a member of the council, and in this position took an active part in directing the military operations in the Carnatic in 1755-59. By the court of directors he was appointed to succeed Lord Pigot in the government of Madras, and in 1757-59 he was commissary-general. In the latter year bad health compelled him to quit India, and he took up his residence in London, where he occupied himself in writing a *History of the Military Transactions of the British Nation in Indostan from 1745*, the first volume appearing in 1763, the second in 1775, and the third in 1778 In acknowledgment of his services he was appointed historiographer to the East India Company with a salary of £400 a year. In

1770 he was chosen a fellow of the Society of Antiquaries. He died at Ealing 13th January 1801.

The *History* is characterized by great clearness and accuracy; but, while the minute enumeration of unimportant details lends vividness to certain portions of his narrative, it produces on the whole a feeling of tediousness, and tends to dull the leading episodes. In 1782 Orme also published *Historical Fragments of the Mogul Empire from the year* 1659, and in 1805 this was reprinted and published along with two other treatises, *The Origin of the English Establishment* and *A General Idea of the Government and People of Hindostan*, and preceded by a short *Life* of the author. He bequeathed several hundred volumes of manuscript collections, and a number of scarce tracts on Oriental subjects, to the library of the East India Company.

ORMONDE, JAMES BUTLER, TWELFTH EARL AND FIRST DUKE OF (1610-1688), was born at London on or about 19th October 1610. He was grandson of Walter, earl of Ormonde, and eldest son of Thomas, Viscount Thurles, and Elizabeth Poyntz.[1] His father having been drowned (15th December 1619) during the lifetime of Earl Walter, he became heir to the title and estates. By some legal artifice the boy was made a royal ward, and James I. at once removed him from his Catholic tutor and placed him in the household of Abbot, archbishop of Canterbury, with whom he stayed until 1626, after which he resided with his grandfather. In 1629, by his marriage with his cousin Elizabeth, the daughter of the earl of Desmond, he put an end to the long-standing quarrel between the families. In 1630 he accompanied the old earl to Carrick, and in 1632 succeeded him in the earldom.

He was already noted, as had been many of his race, for his fine presence and great bodily vigour. His active career began with the arrival of Strafford in 1633. In all ways he was forward in assisting the deputy, but showed such independence and masterfulness of character, along with considerable capacity, that Strafford was for a while doubtful whether to crush or to favour him. Reflecting that Ormonde was one of the richest and probably the most influential of the Irish nobility, he decided to secure his interest; and Ormonde was throughout his government his chief friend and support. Such was the confidence felt in him that in April 1640, when Strafford was with Charles, he was made commander-in-chief of the forces. In August he was appointed lieutenant-general of the kingdom by Strafford, who, upon the death of Wandesford in December, urged Charles to make him deputy. His loyalty to his chief was shown by the vehemence with which he defended him against the attacks of the Irish House of Commons. Upon Strafford's death, and, it is said, at his request, Ormonde was offered the vacant Garter, but refused it for reasons characteristic of the man (Carte). On the arrival of the news of the rebellion in 1641 he received another commission as lieutenant-general from Charles himself, and, though much hampered by the lords justices, he did admirable service in the expedition to the Naas, and in the march into the Pale in 1642, after the rebellion had drawn in the Roman Catholic gentry of English descent. In both of these expeditions the ferocious traditions of Irish warfare were but too faithfully followed. So highly were his services regarded that he was publicly complimented by the English Parliament, who, along with their letter of thanks, sent him a jewel of the value of £620. On 15th April 1642 he gained the battle of Kilrush against Lord Mountgarret, and on 18th March in the following year that of Ross against Preston. In September 1643, the civil war in England having meanwhile broken out, the opposition between Ormonde, who always stood much upon his dignity, and the lords justices became more open and acute. Ormonde, seeing that the large army of Scots in Ulster was both unable to cope with the rebels and was ill-disposed to the king, and that the rebels had been successful at many points, concluded on 15th September the "cessation" with the latter, having power from Charles to treat with the recusants. He had previously, on 16th September 1642, been made a marquis by the king, and had been offered the lord-lieutenantship. This, however, he declined; but his command was made independent of Leicester. Ormonde now threw himself unreservedly into Charles's cause, and at his command sent a body of troops into England, having first exacted an oath of loyalty from the officers (see MONK); it, however, was shortly afterwards routed by Fairfax at the raising of the siege of Nantwich. On the arrival of the news of the "cessation" Charles, anxious to be quit of the Irish problem, which was complicated by the refusal of the Ulster Scots to concur in the "cessation," and desirous at the same time to see the country in safe hands, again offered Ormonde the supreme post, which he now accepted, receiving his commission in January 1644, with special instructions to do all in his power to keep the Scotch army occupied. In all the complications of Scots, Old Irish, Catholic Irish of English race, and Protestants, and in face of the intrigues of the Pope's nuncio as well as of the attempts of the Parliament's commissioners to Ulster to ruin his power, he showed firmness and ability, and especially did his utmost to assist Antrim in his expedition into Scotland. He kept his post until the ground was cut from beneath him by Glamorgan's treaty with the Catholics in 1646, and until it was clear that he could not long hope to hold Dublin against the Irish rebels. He thereupon applied to the English Parliament, gave Dublin into their hands upon terms which protected the interests of both Protestants and Roman Catholics so far as they had not actually entered into rebellion, and sailed for England at the beginning of August 1647. He attended Charles during August and October at Hampton Court, and, after the king's escape to the Isle of Wight, appears to have been his agent in the preliminary negotiation regarding the "engagement" with the Scots. Having good reason to fear that the Parliament intended to secure his person, he hurriedly left England and joined the queen and prince of Wales at Paris in March 1648, where he was of great service in dealing with the agents of the revolted Irish. In September of the same year, the pope's nuncio having been expelled, and affairs otherwise looking favourable, he returned to Ireland to endeavour to unite all parties for the king. He concluded a peace with the rebels on the basis of the free exercise of their religion, proclaimed Charles II., and upheld the royal cause with great vigour though with slight success. He was meanwhile urgent with Charles that he should come in person, but was outwitted and overborne by the Scots and their friends at the king's court. Cromwell having become irresistible, and Charles, under the influence of Argyll, having annulled the peace just concluded, Ormonde returned to France in 1650. He had meanwhile, in September 1649, received the Garter from Charles II.

Ormonde now, though in great straits for want of money, resided in constant attendance upon Charles and the queen-mother at Paris, and accompanied the former when, on his dismissal from France, he went to Aix and Cologne. He appears to have incurred the queen's enmity by frus-

[1] His pedigree extends back to Henry II.'s expedition to Ireland, when Theobald Walter received, in addition to large estates, the hereditary butlership of Ireland, and the prisage of wines, which formed an important part of the vast wealth which the family always possessed. The title of Ormonde appears to have been granted to James the "noble earl," who by the female side was a great-grandson of Edward I. This title, at the request of Henry VIII., the 8th earl resigned to Sir Thomas Boleyn, receiving that of Ossory instead, and regaining that of Ormonde at Boleyn's death. The 9th earl, having borne a chief part in the suppression of the Geraldine rebellion, received a grant of the defeated chieftain's lands, and, in recognition of his further efforts when Henry threw off his allegiance to the pope, the title of Viscount Thurles was given him.

trating the attempts which she made to induce the duke of Gloucester to become Catholic. In 1658, at great risk, he went upon a secret mission into England, to gain trustworthy intelligence as to the chances of a rising.[1] He attended the king at the treaty of Fontarabia, and was actively engaged in the secret transactions immediately preceding the Restoration. In the distribution of honours which followed he had a considerable share: he was at once made lord steward of the household, a privy councillor, lord-lieutenant of Somerset, high steward of Westminster, Kingston, and Bristol, chancellor of Dublin University, Baron Butler of Llanthony, and earl of Brecknock; and on 30th March 1661 he was created duke of Ormonde in the Irish peerage and lord high steward of England. At the same time large grants, in recompense of the fortune he had spent in the royal service, were made by the king, while in the following year the Irish parliament presented him with £30,000. His losses, however, according to Carte, exceeded his gains by a sum almost incredibly enormous. On 4th November 1661 he once more received the lord-lieutenantship of Ireland, and was busily engaged in the settlement of that country until 1664. His heart was in his government, and he vehemently opposed the bill prohibiting the importation of Irish cattle, which struck so fatal a blow at her trade; and, when it was passed, in order to lessen, as he thought, the misfortune, he prohibited the import of Scotch linen, and, further, obtained leave for a certain number of Irish vessels to trade with the foreign enemies of England. He encouraged Irish manufactures and learning to the utmost, and it was to his efforts that the Irish College of Physicians owes its incorporation.

Ormonde's personality had always been a striking one. He had been noted for purity of life and purpose, and for generous and unswerving devotion to the royal cause, when purity and devotion, stimulated by the great argument, were not rare in the court of Charles I. In the court of Charles II. he assumed a still more noteworthy character. At a time when every form of baseness had free course, he figured as almost the sole representative of the high-toned virtues of a nobler generation. Where everything was little he, by force of what is emphatically called "character" far more than by any special ability, was great. The friend and comrade of Strafford, one who had in the royal cause ungrudgingly spent a princely fortune, we see him standing aloof while persons like Bennet intrigued and lied for office or money. Of strict purity of life, he was a living rebuke to the Sedleys and Castlemaines who turned the court into a brothel. Compelled to see the councils of the king guided by dishonour, he acquired over him the influence which Charles was always ready to concede to greatness (*e.g.*, Pepys, 19th May 1668). Proud of the loyalty of his race, which had been unspotted through five centuries, he bore with silent self-respect calumny, envy, and his seven years' loss of court favour, waiting until his master should be shamed into an acknowledgment of the wrong.

He soon became the mark for attack from all that was worst in the court. Buckingham especially did his utmost to undermine his influence. In his almost irresponsible government of Ireland during troublous times Ormonde had no doubt acted now and then in a way which offered advantage to men eager for his overthrow. He had billeted soldiers on civilians, and had executed martial law. The impeachment, however, threatened by Buckingham fell through. Nevertheless, by 1669, constant importunity had had its usual effect upon Charles, and Ormonde was removed from the government of Ireland and from the committee for Irish affairs. He made no complaint, insisted that his sons and others over whom he had influence should retain their posts, and continued to fulfil with dignified persistence the duties of his other offices. The compromise made by Charles with his conscience was marked by a public declaration that, in spite of what had happened, Ormonde had in no degree lost his confidence.

By way of recompense, unsought honours came to him and his family. At the suggestion of Sheldon, Oxford chose him as her chancellor, while Dublin, ignoring Roberts, the new lord-lieutenant, gave to his eldest son Ossory the freedom of the city.

In 1670, while driving through London, he was attacked and dragged out of his carriage by the well-known ruffian Blood, who had been deeply concerned in the attempt upon Dublin Castle in 1663. By whom he was set upon this deed is not known, though Ossory publicly laid it to the charge of Buckingham. Nothing appears to have saved Ormonde's life but the whim of Blood to hang him at Tyburn. The delay thus caused, and Ormonde's vigorous resistance, gave time for rescue. What was the mysterious connexion between Blood and the court has never been discovered: but it is certain that Charles, when Blood was captured, himself asked Ormonde to pardon him.

In 1671 Richard Talbot came over from Ireland in order, if possible, to secure the repeal of the Act of Settlement in favour of the dispossessed Irish gentry. Ormonde was placed on the committee of investigation, and did his utmost to frustrate Talbot's endeavours.

The return of Ormonde to favour, and his appointment to the government of Ireland in 1677, were characteristic both of the times and of Charles himself (Carte). It appears probable that it was the result in a great measure of the desire of James to set up a rival to Monmouth, for whom Shaftesbury had requested the lord-lieutenantship. On his arrival in Ireland he was for a considerable time occupied in placing the revenue and the army upon a proper footing. Upon the outbreak of the Popish terror in England he at once took the most vigorous and comprehensive steps, though with as little harshness as possible, towards rendering the Catholics, who were in the proportion of 15 to 1, powerless (Carte). So mild, however, did his measures appear that they served, in spite of the fact that Ireland was kept in perfect peace, as a reason for an attack upon him in England, which was led by Shaftesbury, and from which he was defended with great spirit by his son Ossory. He kept his course, giving even justice to both religious parties, and Charles had the good sense to refuse to remove him.

Hitherto Ormonde had been singularly fortunate in his family life. But in 1680 he lost his eldest son Ossory, a pure and gallant man, and this was but the beginning of his private sorrows. In 1682 Charles summoned Ormonde to court, and from that time retained him about his person. His first duty was to answer, at the king's request, the memoirs published by the earl of Castlehaven, in which he had reflected upon Charles I. His vigour also during the election of aldermen and during the disputed election of sheriffs for the city after Shaftesbury's acquittal was of the greatest service to the court. On 9th November 1683 an English dukedom was conferred upon him, and in June 1684 he returned to Ireland; scarcely, however, had he set out when intrigues against him once more proved successful, and he was recalled in October. Before, however, he could give up his government to Rochester, Charles II. died, and Ormonde's last act as lord-lieutenant was to proclaim James II. in Dublin. On his return to London he was met with all the pomp and ceremony which, while himself of simple tastes, he had always practised as befitting

[1] For a notice of this see Evelyn's *Diary*, 8th June 1658.

his office and name. He now lived much in retirement at Cornbury (Oxfordshire), signalizing, however, his loyalty to Protestantism and the Church of England by opposing the attempts of James to assume the dispensing power, in spite of which James to his credit refused to take away his offices, and continued to hold him in respect and favour to the last. On Saturday, 21st July 1688, he died quietly of decay, not having, as he rejoiced to know, "outlived his intellectuals." He was buried in Westminster Abbey on the 1st of August.

The principal authorities for Ormonde's life are Carte's *Life* and the Carte papers in the Bodleian, the article "Butler" in the *Biographia Britannica*, Cox's and Leland's *Histories* of Ireland, and the diaries and memoirs of the period. (O. A.)

ORMSKIRK, a market-town of Lancashire, is situated on the Lancashire and Yorkshire Railway, 11 miles north-east of Liverpool. It consists principally of four streets, diverging at right angles from the market-place. The church of St Peter and St Paul is a spacious edifice in various styles of architecture, with a square embattled tower and steeple, and a Saxon window. To the south-east of the church, and divided from it by a screen, is the Derby chapel, the exclusive property of the earls of Derby, whose vault is contained within. A free grammar school was founded about 1614. Among the other public buildings are the sessions-house and police offices, the working-men's institute, the public library, the dispensary, and the union workhouse. Rope and twine making, iron-founding, and brewing are carried on, and the town has long been famous for its gingerbread. The population of the town and urban sanitary district (area 573 acres) was 6651 in 1881 (6127 in 1871).

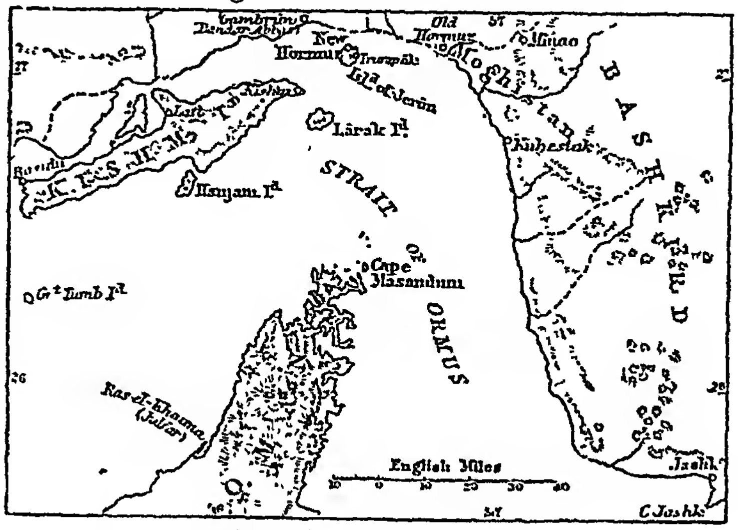
Ormskirk is not found in Domesday; but the parish according to tradition belonged to Orm, the Saxon proprietor of Halton. The name and church existed in the time of Richard I., when the priory of Burscough was founded. The prior and convent obtained from Edward I. a royal charter for a market at the manor of Ormskirk. On the dissolution of the monasteries the manor was granted to the earl of Derby.

ORMUS. This is the European form of the name Hormuz or Hurmúz, applied to a famous city on the shores of the Persian Gulf, which occupied more than one position in the course of history, and which has now long practically ceased to exist. The earliest mention of the name occurs in the voyage of Nearchus (325 B.C.). When that admiral beached his fleet at the mouth of the river Anamis on the shore of Harmozia, a coast district of Karmania, he found the country to be a kindly one, rich in every product except the olive. The Anamis appears to be the river now known as the Mináb, discharging into the Persian Gulf near the entrance of the latter. The name Hormuz is derived by some from that of the Persian god Hormuzd, but it is not unlikely that the original etymology was connected with *khurma*, "a date"; for the meaning of Moghistán, the modern name of the territory Harmozia, is "the region of date-palms." The foundation of the city of Hormuz in this territory is ascribed by one Persian writer to the Sasanian Ardashir Babegán (*c.* 230 A.D.). But it must have existed at an earlier date, for Ptolemy takes note of Ἁρμούζα πόλις (vi. 8).

Hormuz is mentioned by Edrísí, who wrote *c.* 1150, under the title of Hormuz-al-sáhiliah, "Hormuz of the shore" (to distinguish it from inland cities of the same name then existing), as a large and well-built city, the chief mart of Kirmán. Síráf and Kish (Ḳais), farther up the gulf, had preceded it as ports of trade with India, but in the 13th century Hormuz had become the chief seat of this traffic. It was at this time the seat also of a petty dynasty of kings, of which there is a history by one of their number (Túrán Sháh); an abstract of it is given by the Jesuit Teixeira. According to this history the founder of the dynasty was Sháh Mohammed Dirhem-Ku ("the Drachma-coiner"), an Arab chief who crossed the gulf and established himself here. The date is not given, but it must have been before 1100 A.D., as Ruḳnuddín Mahmúd, who succeeded in 1246, was the twelfth of the line. These princes appear to have been at times in dependence necessarily on the atábegs of Fars, and on the princes of Kirmán.

About the year 1300 Hormuz was so severely and repeatedly harassed by raids of Tartar horsemen that the king and his people abandoned their city on the mainland and transferred themselves to the island of Jerún (Organa of Nearchus), about 12 miles westward, and 4 miles from the nearest shore.

The site of the continental or ancient Hormuz was first traced in modern times by Colonel (Sir Lewis) Pelly when resident at Bushire. It stands in the present district of Mináo, several miles from the sea, and on a creek which communicates with the Mináo river,[1] but which is partially silted up and not now accessible for vessels. There remain the traces of a long wharf and of extensive ruins.



Map of the Strait of Ormus.

The island adopted for the new site is of a pear-shape, with the stalk to the north, about 13½ miles in circumference and 4 miles in longest axis. The rounded southern portion is entirely composed of rugged serrated hills rising some 300 feet above the sea, and of an extraordinary variety of vivid colours, a few white peaks, like snow-covered hills, rising high above the general mass, one to a height of 690 feet. The hills, with the remarkable exception (according to the *Persian Gulf Pilot*) of the white peaks, and also of a range on the south and south-east, are all of salt. There is also sulphur. The island was devoid of fresh water except in one small well which exists, or formerly existed, at Ṭúrán Bágh, all the other water in use being collected in cisterns from rainfall; and of vegetation, with the exception of a very little scrub among the hills and of what was produced in the time of the kings by laborious gardening and irrigation at the spot above mentioned. The new city occupied a triangular plain forming the northern part of the island, the southern wall, as its remains still show, being about 2 miles in extent from east to west. A suburb with a wharf or pier, called Ṭúrán Bágh (garden of Ṭúrán) after one of the kings, a name now corrupted to Trumpák, stood about three miles from the town to the south-east.

Odoric (*q.v.*) gives the earliest notice we have of the new city (*c.* 1320). He calls it Ormes, a city strongly fortified and abounding in costly wares, situated on an island 5 miles distant from the main, having no trees and

[1] It is alleged, however, in the *Persian Gulf Pilot*, 1864, that this creek, called Khor Mináb, "is in no way connected with" the river flowing past the town and fort of Mináo or Mináb.

no fresh water, unhealthy, and (as all evidence confirms) incredibly hot. Some years later it was visited more than once by Ibn Batuta, who seems to speak of the old city as likewise still standing. The new Hormuz, called also Jerún (*i.e.*, still retaining the original name of the island), was a great and fine city rising out of the sea, and serving as a mart for all the products of India, which were distributed hence over all Persia. The hills on the island were of rock-salt, from which vases and pedestals for lamps were carved. Near the gate of the chief mosque stood an enormous skull, apparently that of a sperm-whale. The king at this time was Kutbuddín Tahamtan, the son of Ṭúrán Sháh; and the traveller gives a curious description of him, seated on the throne, in patched and dirty raiment, whilst holding a rosary of enormous pearls, procured from the Bahrein fisheries, which at one time or another belonged, with other islands in the gulf and on the Oman shores from Rás-al-ḥadd (C. Rosalgat of the Portuguese) on the ocean round to Julfar on the gulf, to the princes of Hormuz. Abdurazzák, the envoy of Sháh Rukh on his way to the Hindu court of Vijayanagar, was in Hormuz in 1442, and speaks of it as a mart which had no equal, frequented by the merchants of all the countries of Asia, among which he enumerates China, Java, Bengal, Tenasserim, Shahr-í-nao (*i.e.*, Siam), and the Maldives. Nikitin, the Russian (*c.* 1470), gives a similar account; he calls it "a vast emporium of all the world."

In September 1507 the king of Hormuz, after for some time hearing of the terrible foe who was carrying fire and sword along the shores of Arabia, saw the squadron of Alphonso d'Albuquerque appear before his city, an appearance speedily followed by extravagant demands, by refusal of these from the ministers of the young king, and by deeds of matchless daring and cruelty on the part of the Portuguese, which speedily broke down resistance. The king acknowledged himself tributary to Portugal, and gave leave to the Portuguese to build a castle, which was at once commenced on the northern part of the island, commanding the city and the anchorage on both sides. But the mutinous conduct and desertion of several of Albuquerque's captains compelled him suddenly to abandon the enterprise; and it was not till 1514, after the great leader had captured Goa and Malacca, and had for five years been viceroy, that he returned to Hormuz (or Ormuz, as the Portuguese called it), and, without encountering resistance to a name now so terrible, laid his grasp again on the island and completed his castle. For more than a century Ormuz remained practically in the dominions of Portugal, though the hereditary prince, paying from his revenues a tribute to Portugal (in lieu of which eventually the latter took the whole of the customs collections), continued to be the instrument of government. The position of things during the Portuguese rule may be understood from the description of Cesare de' Federici, a Venetian merchant who was at Ormuz about 1565. After speaking of the great trade in spices, drugs, silk and silk stuffs, and pearls of Bahrein, and in horses for export to India, he says the king was a Moor (*i.e.*, Mohammedan), chosen by and subordinate to the Portuguese. "At the election of the king I was there and saw the ceremonies that they use. . . . The old king being dead, the captain of the Portugals chooseth another of the blood-royal, and makes this election in the castle with great ceremony. And when he is elected the captain sweareth him to be true . . . to the K. of Portugal as his lord and governor, and then he giveth him the sceptre regal. After this . . . with great pomp . . . he is brought into the royal palace in the city. The king keeps a good train and hath sufficient revenues, . . . because the captain of the castle doth maintain and defend his right . . . he is honoured as a king, yet he cannot ride abroad with his train, without the consent of the captain first had" (in Hakluyt).[1]

The rise of the English trade and factories in the Indian seas in the beginning of the 17th century led to constant jealousies and broils with the Portuguese, and the successful efforts of the English company to open traffic with Persia especially embittered their rivals, to whom the possession of Ormuz had long given a monopoly of that trade. The officers of Sháh Abbás, who looked with a covetous and resentful eye on the Portuguese occupation of such a position, were strongly desirous of the aid of English ships in attacking Ormuz. During 1620 and 1621 the ships of Portugal and of the English company had more than once come to action in the Indian seas, and in November of the latter year the council at Surat had resolved on what was practically maritime war with the Portuguese flag. There was hardly a step between this and the decision come to in the following month to join with "the duke of Shiráz" (Imám Kúlí Khán, the governor of Fars) in the desired expedition against Ormuz. There was some pretext of being forced into the alliance by a Persian threat to lay embargo on the English goods at Jashk; but this seems to have been only brought forward by the English agents when, at a later date, their proceedings were called in question. The English crews were at first unwilling to take part in what they justly said was "no merchandizing business, nor were they engaged for the like," but they were persuaded, and five English vessels aided, first, in the attack of Kishm, where (at the east end of the large island so called) the Portuguese had lately built a fort,[2] and afterwards in that of Ormuz itself. The latter siege was opened on the 18th February 1622, and continued to 1st May, when the Portuguese, after a gallant defence of ten weeks, surrendered. It is to be recollected that Portugal was at this time subject to the crown of Spain, with which England was at peace; indeed, it was but a year later that the prince of Wales went on his wooing adventure to the Spanish court. The irritation there was naturally great, though it is surprising how little came of it. The company were supposed (apparently without foundation) to have profited largely by the Ormuz booty; and both the duke of Buckingham and the king claimed to be "sweetened," as the record phrases it, from this supposed treasure. The former certainly received a large bribe (£10,000). The conclusion of the transaction with the king was formerly considered doubtful; but entries in the calendar of East India papers lately published seem to show that James received an equal sum.[3]

Ormuz never recovered from this blow. The Persians transferred their establishments to Gombroon on the mainland, about 12 miles to the north-west, which the king had lately set up as a royal port under the name of Bandar Abbási. The English stipulations for aid had embraced an equal division of the customs duties. This division was apparently recognized by the Persians as applying to the new Bandar, and, though the trade with Persia was constantly decaying and precarious, the company held to their factory at Gombroon for the sake of this claim to revenue, which of course was most irregularly paid. In 1683-84 the amount of debt due to the company in Persia, including their proportion of customs duties, was reckoned at a million sterling. As late as 1690-91 their right seems to have been admitted, and a payment of 3195 sequins was received by them on this account. The factory at Gom-

[1] In Barros, *Dec.* II., book x. c. 7, there is a curious detail of the revenue and expenditure of the kingdom of *Ormuz*, which would seem to exhibit the former as not more than £100,000.

[2] The attack on Kishm was notable in that one of the two Englishmen killed there was the great navigator Baffin.

[3] *Colonial Series, E. Indies*, by Sainsbury, vol. iii. *passim*, especially see pp. 296 and 329.

broon lingered on till 1759, when it was seized by two French ships of war under Comte d'Estaing. It was re-established, but at the time of Niebuhr's visit to the gulf a few years later no European remained. Niebuhr mentions that in his time (*c.* 1765) Mulla 'Ali Sháh, formerly admiral of Nádir Sháh, was established on the island of Ormuz and part of Kishm as an independent chief. On Ormuz the solidly-built Portuguese castle still stands, and some of the immense water-tanks, with fresh water in them, in almost perfect integrity. "With their arched and groined roofs, supported on heavy pillars, they appeared like the crypts of some great cathedral" (Colomb, *Slave-catching in the Indian Ocean*, 1873, pp. 142-143). Of the city hardly anything stands except a minaret,[1] by some called a lighthouse, but the traces of buildings are numerous and extensive. A small band of fishermen and salt-diggers living in mat huts and a small guard from Muscat in the castle form the sole population. The island is, with Kishm and other places near, rented from Persia by the sultan of Muscat, chiefly for the salt and sulphur.

[1] Fraser heard that this was erected by Sháh Abbás after the capture.
